

LP5569 Nine-Channel I²C RGB LED Driver With Engine Control and Charge Pump

1 Features

- Supply Voltage Range: 2.5 V–5.5 V
- Nine High-Accuracy Current Sinks
 - 25.5 mA Maximum per Channel
 - 8-Bit Individual Current Control
 - 12-Bit 20-kHz Internal Individual PWM Control Without Audio Noise
- Three Programmable LED Engines
 - Independent Illumination Control Without Active Microcontroller Control
 - Synchronization Among Multiple Devices
 - Up to 256 Instructions in SRAM Memory for Storing Sequences of Lighting Patterns
 - LP5523- and LP55231-Device-Compatible Command Set
- Flexible Dimming Control
 - I²C Dimming Control
 - PWM Direct-Input Dimming
 - PWM Input Frequency: 100-Hz to 20-kHz
- Adaptive High-Efficiency Charge-Pump Control for Driving High-V_F LEDs With Low Battery Voltage
- Master Fader Control Allows Dimming of Multiple LEDs by Writing to Only One Register to Reduce the I²C Bus Traffic
- 2- μ A Low Standby Current and 10- μ A in Automatic Power-Save Mode When LEDs Are Inactive
- POR, UVLO, and TSD Protection

2 Applications

LED Lighting, Indicator Lights, and Fun Lights for:

- Smart Speaker
- Smart Home Appliance
- Doorbell
- Electric Lock
- Smoke Detector
- Thermostat
- Set-Top Box
- Smart Router
- Bluetooth® Headset
- Cell Phone

3 Description

The LP5569 device is a programmable, easy-to-use 9-channel I²C LED driver designed to produce lighting effects for various applications. The LED driver is equipped with an internal SRAM memory for user-programmed sequences and three programmable LED engines, which allow operation without processor control. Autonomous operation reduces system power consumption when the processor is put in sleep mode.

A high-efficiency charge pump enables the driving of LEDs with high V_F, even with 2.5-V input voltage. The LP5569 LED driver maintains good efficiency over a wide operational voltage range by autonomously selecting the best charge-pump gain based on LED forward voltage requirements.

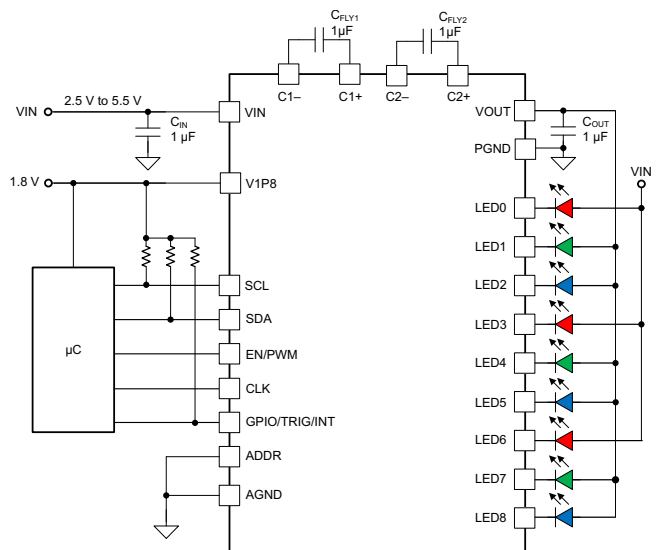

The LP5569 device enters power-save mode when LEDs are not active, lowering idle-current consumption considerably. A flexible digital interface allows the connection of up to eight LP5569 devices in the same system, which supports synchronization of the lighting effects among all devices.

Device Information⁽¹⁾

PART NUMBER	PACKAGE	BODY SIZE (NOM)
LP5569	WQFN (24)	4.00 mm x 4.00 mm

(1) For all available packages, see the orderable addendum at the end of the data sheet.

5 Device Comparison Table

PART NUMBER	GROUP	I ² C SLAVE ADDRESS
LP5569	0	32h–35h and 40h (see I²C Slave Addressing)
LP5569A	1	42h–45h and 40h (see I²C Slave Addressing)

6 Pin Configuration and Functions

Pin Functions

PIN		TYPE ⁽¹⁾	DESCRIPTION
NAME	NO.		
ADDR	20	I	I ² C slave-address selection pin. See I²C Slave Addressing for more details. This pin must not be left floating.
AGND	4	G	Analog and digital ground. Connect to PGND, exposed thermal pad, and common ground plane.
C1–	24	A	Negative pin of charge-pump flying capacitor 1. If charge pump is not used, this pin must be left floating.
C1+	2	A	Positive pin of charge-pump flying capacitor 1. If charge pump is not used, this pin must be left floating.
C2–	23	A	Negative pin of charge-pump flying capacitor 2. If charge pump is not used, this pin must be left floating.
C2+	1	A	Positive pin of charge-pump flying capacitor 2. If charge pump is not used, this pin must be left floating.
CLK	6	I, OD	Clock input/output. By default this pin is a clock input. If not used, this pin must be connected to GND or VIN.
EN/PWM	5	I	Chip enable and PWM input pin.

(1) A: analog pin; G: ground pin; P: power pin; I: input pin; OD: open-drain output pin

Pin Functions (continued)

PIN		TYPE ⁽¹⁾	DESCRIPTION
NAME	NO.		
GPIO/TRIG/INT	7	I, OD	General-purpose input or open-drain output, or trigger input or open-drain output, or interrupt open-drain output. This pin function is configured in the I ² C registers. By default this pin is a general-purpose output (open-drain) and can be left floating if not used.
LED0	19	A	LED current sink 0. If not used, this pin can be left floating.
LED1	18	A	LED current sink 1. If not used, this pin can be left floating.
LED2	17	A	LED current sink 2. If not used, this pin can be left floating.
LED3	16	A	LED current sink 3. If not used, this pin can be left floating.
LED4	15	A	LED current sink 4. If not used, this pin can be left floating.
LED5	14	A	LED current sink 5. If not used, this pin can be left floating.
LED6	13	A	LED current sink 6. If not used, this pin can be left floating.
LED7	12	A	LED current sink 7. If not used, this pin can be left floating.
LED8	11	A	LED current sink 8. If not used, this pin can be left floating.
PGND	21	G	Charge-pump power ground. Connect to AGND, exposed thermal pad, and common ground plane.
SCL	9	I	I ² C bus clock line. If not used, this pin must be connected to GND or VIN.
SDA	8	I, OD	I ² C bus data line. If not used, this pin must be connected to GND or VIN.
V1P8	10	P	Input power for digital circuitry.
VIN	3	P	Input power, a 1- μ F capacitor must be connected between PGND and this pin.
VOUT	22	A	Charge-pump output voltage. If charge pump is used, a 1- μ F capacitor must be connected between PGND and this pin. If charge pump is not used or is used in 1x mode only, the capacitor can be omitted.
Exposed thermal pad	—	—	Must be connected to AGND (pin 4), PGND (pin 21), and common ground plane. See Layout Example . Must be soldered to achieve appropriate power dissipation and mechanical reliability.

7 Specifications

7.1 Absolute Maximum Ratings

over operating ambient temperature range (unless otherwise noted)⁽¹⁾

	MIN	MAX	UNIT
Voltage on VIN, CLK, ADDR, EN/PWM, GPIO/TRIG/INT, SCL, SDA, VOUT ⁽²⁾	-0.3	6	V
Voltage on LED0 to LED8, C1-, C2-, C1+, C2+	-0.3	$V_{VIN} + 0.3$ V with 6 V max.	V
Voltage on V1P8	-0.3	2	V
Continuous power dissipation	Internally limited	Internally limited	
Junction temperature, T_{J-MAX}	-40	125	°C
Storage temperature, T_{stg}	-65	150	°C

- (1) Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under *Recommended Operating Conditions*. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.
- (2) VOUT cannot be forced to a power supply during device shutdown.

7.2 ESD Ratings

		VALUE	UNIT
$V_{(ESD)}$ Electrostatic discharge	Human-body model (HBM), per ANSI/ESDA/JEDEC JS-001 ⁽¹⁾	±2500	V
	Charged-device model (CDM), per JEDEC specification JESD22-C101 ⁽²⁾	±250	

- (1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.
- (2) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

7.3 Recommended Operating Conditions

over operating ambient temperature range (unless otherwise noted)

	MIN	MAX	UNIT
Input voltage on VIN	2.5	5.5	V
Voltage on LED0 to LED8, C1-, C2-, C1+, C2+, VOUT	0	V_{VIN}	V
Voltage on CLK, ADDR, EN/PWM, GPIO/TRIG/INT, SDA, SCL	0	V_{VIN}	V
Input voltage on V1P8	1.65	1.95	V
Output current on VOUT	0	160	mA
Operating ambient temperature, T_A ⁽¹⁾	-40	85	°C

- (1) In applications where high power dissipation and/or poor PCB cooling status is present, the maximum ambient temperature might require derating. Maximum ambient temperature (T_{A-MAX}) is dependent on the maximum operating junction temperature ($T_{J-MAX-OP} = 125^\circ\text{C}$), the maximum power dissipation of the device in the application (P_{D-MAX}), and the junction-to ambient thermal resistance of the device in the application ($R_{\theta JA}$), as given by the equation: $T_{A-MAX} = T_{J-MAX-OP} - (R_{\theta JA} \times P_{D-MAX})$.

7.4 Thermal Information

THERMAL METRIC ⁽¹⁾		LP5569	UNIT
		RTW (WQFN)	
		24 PINS	
$R_{\theta JA}$	Junction-to-ambient thermal resistance	35.8	°C/W
$R_{\theta JC(top)}$	Junction-to-case (top) thermal resistance	26.7	°C/W
$R_{\theta JB}$	Junction-to-board thermal resistance	13.1	°C/W
Ψ_{JT}	Junction-to-top characterization parameter	0.4	°C/W
Ψ_{JB}	Junction-to-board characterization parameter	13.1	°C/W
$R_{\theta JC(bot)}$	Junction-to-case (bottom) thermal resistance	4.6	°C/W

- (1) For more information about traditional and new thermal metrics, see [Semiconductor and IC Package Thermal Metrics](#).

7.5 Electrical Characteristics

Unless otherwise noted, specifications apply to the LP5569 device in a circuit per the typical application diagram for the single device with $V_{VIN} = 3.6\text{ V}$, $V_{1P8} = 1.8\text{ V}$, $V_{EN/PWM} = V_{VIN}$, $C_{IN} = C_{OUT} = C_{FLY1} = C_{FLY2} = 1\text{ }\mu\text{F}$. Typical (TYP) values apply for $T_A = 25^\circ\text{C}$ and minimum (MIN) and maximum (MAX) apply over the operating ambient temperature range ($-40^\circ\text{C} < T_A < 85^\circ\text{C}$).

PARAMETER		TEST CONDITIONS	MIN	TYP	MAX	UNIT
I_{VIN}	Standby supply current	$V_{EN/PWM} = 0\text{ V}$, chip_en (bit) = 0		0.2	1	μA
		$V_{EN/PWM} = 3.3\text{ V}$, chip_en (bit) = 0, external CLK not running		1	2	
		$V_{EN/PWM} = 3.3\text{ V}$, chip_en (bit) = 0, external CLK running		2	4	
	Normal-mode supply current	External CLK running, charge pump and current sinks disabled		56	70	μA
		Charge pump in 1x mode, no load, current sinks disabled		65	90	
		Charge pump in 1.5x mode, no load, current-sink outputs disabled		1.8		mA
	Power-save mode supply current	External CLK running, see Automatic Power-Save Mode		10	15	μA
Internal oscillator running			10	15		
I_{V1P8}	Standby supply current	$V_{EN/PWM} = 0\text{ V}$, chip_en (bit) = 0		0.2	1	μA
		$V_{EN/PWM} = 3.3\text{ V}$, chip_en (bit) = 0, external CLK not running		0.2	2	μA
		$V_{EN/PWM} = 3.3\text{ V}$, chip_en (bit) = 0, external CLK running		1	4	μA
	Normal-mode supply current	External CLK running, charge pump and current sinks disabled		174	190	μA
		Charge pump in 1x mode, no load, current sinks disabled		174	190	μA
		Charge pump in 1.5x mode, no load, current-sink- outputs disabled		180		μA
	Powersave-mode supply current	External CLK running		1	5	μA
Internal oscillator running			1	5	μA	
f_{osc}	32-kHz internal oscillator frequency accuracy	$T_A = 25^\circ\text{C}$	-10%		10%	
	10-MHz internal oscillator frequency accuracy		-7%		7%	
V_{UVLO}	Undervoltage lockout	V_{VIN} falling		2.2		V
		V_{VIN} rising		2.3		

7.6 Charge-Pump Electrical Characteristics

PARAMETER		TEST CONDITIONS	MIN	TYP	MAX	UNIT
R_{OUT}	Charge-pump output resistance	Gain = 1x, $V_{VIN} = 4.2\text{ V}$		1		Ω
		Gain = 1.5x, $V_{VIN} = 3.7\text{ V}$		3.5		
V_{OUT}		$V_{VIN} = 3.7\text{ V}$, $I_{OUT} = 160\text{ mA}$, gain = 1.5x	4.41	4.5	4.59	V
f_{sw}	Switching frequency			1.25		MHz
I_{CL}	Output current limit	$V_{OUT} = 0\text{ V}$, $V_{VIN} = 3.7\text{ V}$, CP_CONFIG = 0xFF		600		mA
t_{ON}	V_{OUT} turnon time	$I_{OUT} = 0\text{ mA}$, $V_{IN} \geq 3\text{ V}$, $V_{OUT} > 4.1\text{ V}$, gain = 1.5x		100		μs
I_{OUT}	Maximum output current	$V_{VIN} > 3.1\text{ V}$, V_{OUT} dropped 10%, gain = 1.5x		200		mA
		$V_{IN} > 2.5\text{ V}$, V_{OUT} dropped 10%, gain = 1.5x		150		

7.7 LED Current Sinks Electrical Characteristics

PARAMETER		TEST CONDITIONS	MIN	TYP	MAX	UNIT
$I_{LEAKAGE}$	Leakage current (LED0 to LED8)	PWM = 0%, $V_{LED} = 5\text{ V}$			1	μA
I_{MAX}	Maximum sink current		24.5	25.5	26.5	mA
I_{LED_ACC}	Sink current accuracy ⁽¹⁾	Current set to 17.5 mA. PWM = 100%	-4.5%		4.5%	
I_{LED_MATCH}	Matching ⁽¹⁾	Current set to 17.5 mA		1%	2.5%	
f_{LED}	LED switching frequency			19.5		kHz
V_{SAT}	Saturation voltage ⁽²⁾	Output current set to 25.5 mA		90	110	mV

- (1) Output-current accuracy is the difference between the actual value of the output current and the programmed value of this current. Matching is the maximum difference from the average. For the constant-current outputs on the device (LED0 to LED8), the following are determined: the maximum output current (MAX), the minimum output current (MIN), and the average output current of all outputs (AVG). The matching number is calculated: $(MAX - MIN) / AVG$. The typical specification provided is the most likely norm of the matching figure for all devices. Note that some manufacturers have different definitions in use.
- (2) Saturation voltage is defined as the voltage when the LED current has dropped 10% from the value measured at 1 V.

7.8 Logic Interface Characteristics

PARAMETER		TEST CONDITIONS	MIN	TYP	MAX	UNIT
LOGIC INPUT (EN/PWM, SCL, ADDR)						
V_{IL}	Input low level				0.4	V
V_{IH}	Input high level		1.25			V
I_{IKG}	Input leakage current	$V_I \leq V_{VIN}$	-1		1	μA
LOGIC OUTPUT (SDA, GPIO/TRIG/INT, CLK)						
V_{IL}	Input low level	Pin configured as input			0.4	V
V_{IH}	Input high level	Pin configured as input	1.25			V
I_{IKG}	Input leakage current	Pin configured as input, $V_{VIN} = 5.5\text{ V}$, $V_I \leq V_{VIN}$	-1		1	μA
V_{OL}	Output low level	$I_{PULLUP} = 3\text{ mA}$		0.2	0.5	V
I_L	Output leakage current	Pin configured as output, Hi-Z state			1	μA

7.9 Timing Requirements (EN/PWM)

		MIN	TYP	MAX	UNIT
t_{EN}	Enable time, EN/PWM first rising edge until first I ² C access		2	3	ms
$t_{EN_TIMEOUT}$	EN timeout, EN/PWM = low time while in standby mode (enable function)		15		ms
$t_{PWM_TIMEOUT}$	PWM timeout, EN/PWM = low time while in normal mode (PWM function)		15		ms
PWM_{res}	Resolution for EN/PWM input when configured as PWM, $f_{PWM} = 10\text{ kHz}$		10		bits

7.10 Serial-Bus Timing Requirements (SDA, SCL), See Figure 1

 I²C fast mode

		MIN	MAX	UNIT
f_{SCL}	Clock frequency	0	400	kHz
1	Hold time (repeated) START condition	0.6		μ s
2	Clock low time	1.3		μ s
3	Clock high time	600		ns
4	Setup time for a repeated START condition	600		ns
5	Data hold time	0		ns
6	Data setup time	100		ns
7	Rise time of SDA and SCL	$20 + 0.1C_b$	300	ns
8	Fall time of SDA and SCL	$15 + 0.1C_b$	300	ns
9	Setup time for STOP condition	600		ns
10	Bus-free time between a STOP and a START condition	1.3		μ s
C_b	Capacitive load for each bus line	10	200	pF

7.11 External Clock Timing Requirements (CLK), See Figure 2

over operating ambient temperature range (unless otherwise noted)

		MIN	TYP	MAX	UNIT
f_{CLK}	Clock frequency		32.7		kHz
t_{CLKH}	High time	6			μ s
t_{CLKL}	Low time	6			μ s
t_r	Clock rise time, 10% rising edge to 90% rising edge			2	μ s
t_f	Clock fall time, 90% falling edge to 10% falling edge			2	μ s

8 Detailed Description

8.1 Overview

The LP5569 device is a fully integrated lighting management unit for producing lighting effects for various LED applications. The LP5569 device includes all necessary power management, low-side current sinks, two-wire serial I²C-compatible interface, and programmable LED engines. The overall maximum current for each of the nine drivers is set with 8-bit resolution. The LP5569 device controls LED luminance with a pulse-width modulation (PWM) scheme with a resolution of 12 bits at 20 kHz, which is achieved by using 3-bit dithering.

8.1.1 Programming

The LP5569 device provides flexibility and programmability for dimming and sequencing control. Each LED can be controlled directly and independently through the serial interface, or LED drivers can be grouped together for preprogrammed flashing patterns. The device has three independent program execution engines. Each engine can control 1 to 9 LED driver outputs, but more than one engine cannot simultaneously control the same LED driver output. Any engine can be used as the master fader for all three engines.

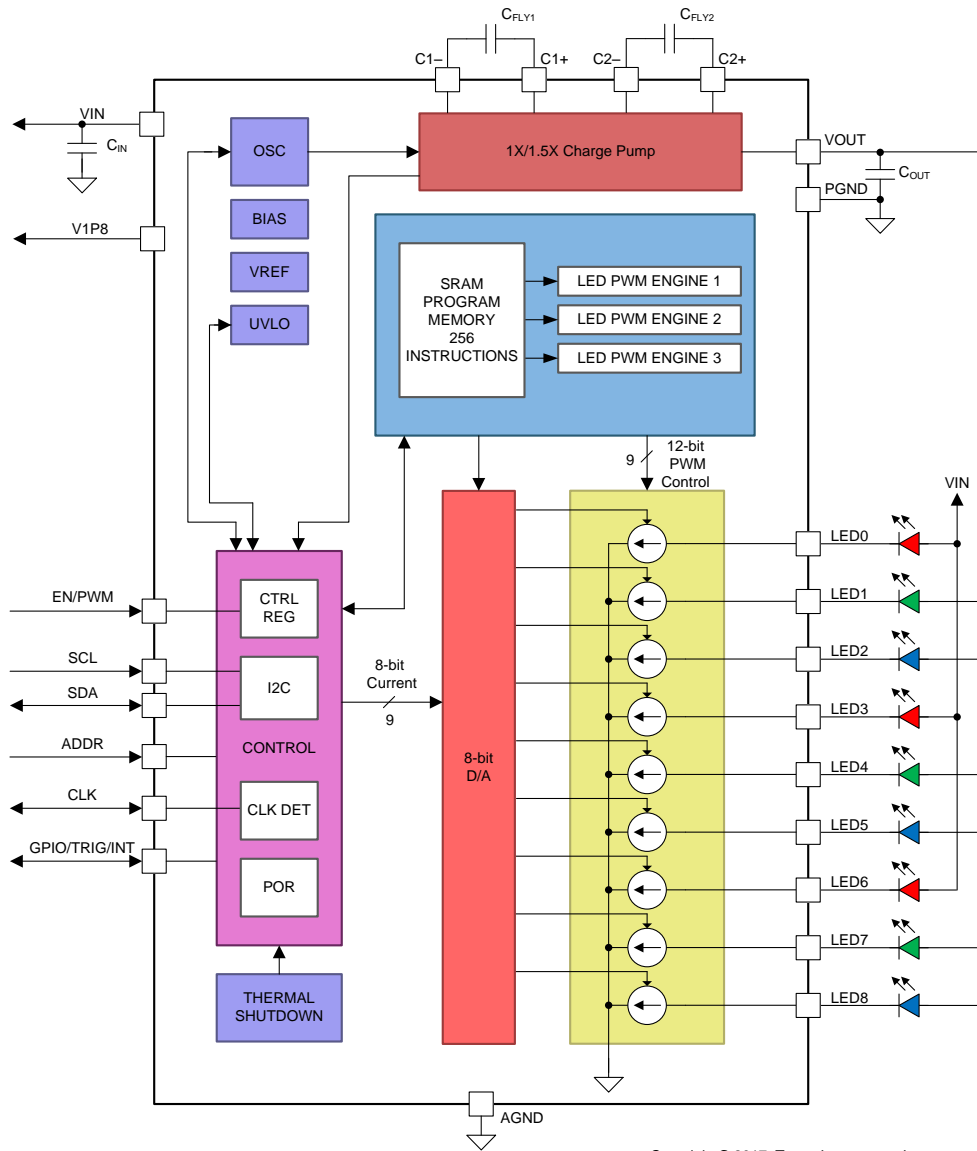

8.1.2 Energy Efficiency

An integrated 1x or 1.5x charge pump with adaptive control provides supply voltage for LEDs when operating with low input voltage. Because the LED drivers are low-side sinks, some or all LEDs can be powered from an external source if available. The LP5569 device has very low standby current and an automatic power-save mode when the LEDs are inactive.

8.1.3 Protection Features

Protection features include power-on reset, charge-pump input-current limiter, thermal shutdown (TSD), and undervoltage lockout (UVLO).

8.2 Functional Block Diagram

8.3 Feature Description

8.3.1 Current Sinks

8.3.1.1 Overview

The LP5569 LED drivers are constant-current sources. Maximum output-current scale can be programmed by control registers up to 25.5 mA. The overall maximum current is set by 8-bit output current-control registers with 100- μ A step size. Each of the 9 LED drivers has a separate output-current control register. The LED luminance pattern (dimming) is controlled with a PWM technique, which has 12-bit resolution during ramping and 8-bit user control. The LED current-sink PWM frequency is 20 kHz.

High 20-kHz PWM frequency and 12-bit control accuracy are achieved by using 3-bit dithering for PWM control. There is a 9-bit pure PWM resolution generated in the PWM generators, and one least-significant bit (1 LSB) is toggled in eight periods to output a smaller average step. For 3-bit dithering, every eighth pulse is made 1 LSB longer to increase the average value by 1 / 8th. Figure 12 shows an example of 9-bit PWM value, step of 4 / 8 (0.5) and its 12-bit representation.

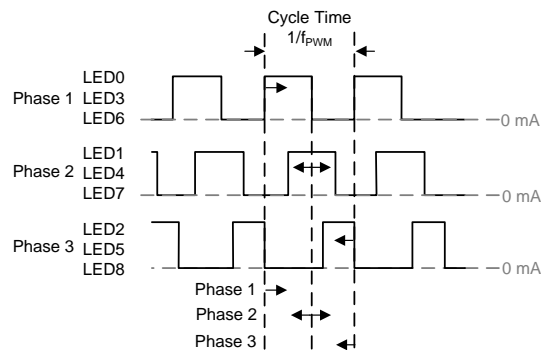

Figure 12. Dithering

A phase-shift PWM scheme allows delaying the time when each LED driver is active. When the LED drivers are not activated simultaneously, the peak load current from the charge-pump output is greatly decreased. This also reduces input-current ripple and ceramic-capacitor audible ringing. LED drivers are grouped into three different phases. In phase 1, the rising edge of the PWM pulse is fixed in time. In phase 2, the middle point of the PWM pulse is fixed, and the pulse spreads to both directions when PWM duty cycle is increased. Phase 3 has a fixed falling edge, that is, the rising edge of the pulse is changed when the duty cycle changes.

Copyright © 2016, Texas Instruments Incorporated

Figure 13. LED Phase Shift

LED dimming is controlled according to an exponential or linear scale (see Figure 14) In exponential mode, the PWM output percent can be approximated by the following two equations:

- Less than or equal to code 64: $y = 0.0125x - 0.0066$.
- Greater than code 64: $y = 0.7835e^{0.0217x}$

Feature Description (continued)

Figure 14. 8-Bit User PWM Control, Exponential and Linear Dimming

8.3.1.2 Controlling the Low-Side Current Sinks

8.3.1.2.1 Direct Register Control

All LP5569 LED drivers, LED0 to LED8, can be controlled independently through the two-wire serial I²C-compatible interface. For each low-side driver there is an 8-bit PWM control register which can be used to control the LED PWM duty-cycle value. This register cannot be written when the program execution engine is active, which could result in undesirable behavior. Care should be taken to update these registers only when the program execution engine is idle.

8.3.1.2.2 Controlling by Program Execution Engines

Engine control is used when the user wants to create programmed sequences. The program execution engine updates the direct-control registers when active. Therefore, if the user has set the PWM register to a certain value, it is automatically overridden when the program execution engine controls the driver. LED control and program-execution-engine operation is described in [Programming](#).

8.3.1.2.3 Master Fader Control

In addition to LED-by-LED PWM register control, the LP5569 device is equipped with a master-fader control, which allows the user to fade in or fade out multiple LEDs from the EN/PWM pin or by writing to the master fader registers. This is a useful function to minimize serial bus traffic between the MCU and the LP5569 device. The LP5569 device has three master fader registers, so it is possible to form three master fader groups. Either writing master fader registers through the I²C interface directly or through LED engine control can set the master fader register values. The final output PWM duty cycle is the PWM register duty-cycle value multiplied by the duty-cycle value of the master fader register.

Feature Description (continued)

Figure 15. Simplified Data Flow of Master Fader

8.3.1.2.3.1 PWM Master Fader on EN/PWM Pin

The EN/PWM pin provides a dual-function input. On power up, the pin functions as the device enable (EN) function, where the first rising edge enables the LP5569 device. After the chip_en bit is set high in the CONFIG register, the pin is reconfigured for PWM master-fader control of the LEDs. The LEDx_CONTROL register (addresses 07h–0Fh) MF_MAPPINGx bits = 5h configures LEDx for PWM control.

The PWM input is a sampled input which converts the input duty-cycle information into an 11-bit code. The use of a sampled input eliminates any noise and current ripple that is typical of traditional PWM-controlled LED drivers. The PWM input uses logic-level thresholds with $V_{IH_MIN} = 1.25\text{ V}$ and $V_{IL_MAX} = 0.4\text{ V}$. Because this is a sampled input, there are limits on the maximum PWM input frequency as well as the resolution that can be achieved.

8.3.1.2.3.2 PWM Master Fader Resolution and Input Frequency Range

The PWM input frequency range is 100 Hz to 20 kHz. To achieve the full 11-bit maximum resolution of PWM duty cycle to the code, the input PWM duty cycle must be ≥ 11 bits, and the PWM sample period ($1 / f_{SAMPLE}$) must be smaller than the minimum PWM input pulse duration. Figure 16 shows the possible brightness code resolutions based on the input PWM frequency.

Figure 16. PWM Resolution vs PWM Input Frequency

Feature Description (continued)

8.3.1.2.3.3 PWM Master Fader Hysteresis

To prevent jitter on the input PWM signal from feeding through the PWM path and causing oscillations in the LED current, the LP5569 device offers seven selectable hysteresis settings. The hysteresis works by forcing a specific number of 11-bit LSB code transitions to occur in the input duty cycle before the LED current changes. Table 1 describes the hysteresis. The hysteresis only applies during a change in direction of brightness currents. Once the change in direction has taken place, the PWM input must overcome the required LSB(s) of the hysteresis setting before the brightness change takes effect. Once the initial hysteresis has been overcome and the direction in brightness change remains the same, the PWM-to-current response changes with no hysteresis.

Table 1. PWM Input Hysteresis

HYSTERESIS SETTING (0x80 bits [2:0])	MIN. CHANGE IN PWM PULSE DURATION (Δt) REQUIRED TO CHANGE LED CURRENT, AFTER DIRECTION CHANGE (for $f_{PWM} < 11.7$ kHz)	MIN. CHANGE IN PWM DUTY CYCLE (ΔD) REQUIRED TO CHANGE LED CURRENT AFTER DIRECTION CHANGE	MIN (ΔI_{LED}), INCREASE FOR INITIAL CODE	
			EXPONENTIAL MODE	LINEAR MODE
000 (0 LSB)	$1 / (f_{PWM} \times 2047)$	0.05%	0.3%	0.05%
001 (1 LSB)	$1 / (f_{PWM} \times 1023)$	0.1%	0.61%	0.1%
010 (2 LSB)	$1 / (f_{PWM} \times 511)$	0.2%	1.21%	0.2%
011 (3 LSB)	$1 / (f_{PWM} \times 255)$	0.39%	2.4%	0.39%
100 (4 LSB)	$1 / (f_{PWM} \times 127)$	0.78%	4.74%	0.78%
101 (5 LSB)	$1 / (f_{PWM} \times 63)$	1.56%	9.26%	1.56%
110 (6 LSB)	$1 / (f_{PWM} \times 31)$	3.12%	17.66%	3.12%

- D is $t_{JITTER} \times f_{PWM}$ or equal to #LSB's = $\Delta D \times 2048$ codes.
- For 11-bit resolution, #LSBs is equal to a hysteresis setting of $LN(\#LSB's)/LN(2)$.
- For example, with a t_{JITTER} of 1 μs and a f_{PWM} of 5 kHz, the hysteresis setting should be: $LN(1 \mu s \times 5 \text{ kHz} \times 2048)/LN(2) = 3.35$ (4 LSBs).

Figure 17. PWM Hysteresis Example

8.3.1.2.4 EN/PWM Input Timeout

The EN/PWM input timeout feature has two operating modes as follows:

- STANDBY state: EN/PWM low for > 15 ms shuts down the LP5569 device and returns to the DISABLED state (see [Figure 20](#)).

8.3.2 Charge Pump

8.3.2.1 Overview

The LP5569 device includes a pre-regulated switched-capacitor charge pump with a programmable voltage multiplication of 1x or 1.5x. In 1.5x mode, by combining the principles of a switched-capacitor charge pump and a linear regulator, a regulated 4.5-V output is generated from the VIN input within its normal voltage range. A two-phase non-overlapping clock, generated internally, controls the operation of the charge pump. During the charge phase, both flying capacitors (CFLY1 and CFLY2) are charged from input voltage. In the pump phase that follows, the flying capacitors are discharged to the output. A traditional switched-capacitor charge pump operating in this manner uses switches with very low on-resistance, ideally 0 Ω, to generate an output voltage that is 1.5x the input voltage. The LP5569 device regulates the output voltage by controlling the resistance of the input-connected pass-transistor switches in the charge pump.

8.3.2.2 Pre-Regulation

The very low input-current ripple of the LP5569 device, resulting from internal pre-regulation, adds minimal noise to the input line. The core of the LP5569 device is very similar to that of a basic switched-capacitor charge pump: it is composed of switches and two flying capacitors (external). Regulation is achieved by controlling the current through the switches connected to the VIN pin (one switch in each phase). The regulation occurs before the voltage multiplication, giving rise to the term *pre-regulation*. It is pre-regulation that eliminates most of the input-current ripple that is a typical and undesirable characteristic of a many switched-capacitor converters.

8.3.2.3 Input Current Limit

The LP5569 device contains current-limit circuitry that protects the device in the event of excessive input current and/or output shorts to ground. The input current is limited to 600 mA (typical) when the output is shorted directly to ground. When the LP5569 device is current limiting, power dissipation in the device is likely to be quite high. In this event, thermal cycling should be expected.

8.3.2.4 Output Discharge

The LP5569 device provides a feature to discharge the charge-pump output capacitor. The charge-pump output pulldown is not enabled when the MISC2 register (address 33h) CP_DIS_DISCH bit = 1. The charge pump output pulldown is enabled when the CP_DIS_DISCH bit = 0. The pulldown draws a minimal current from the output capacitor (300 μA typical) when in the SHUTDOWN and STANDBY states.

8.3.2.5 Controlling the Charge Pump

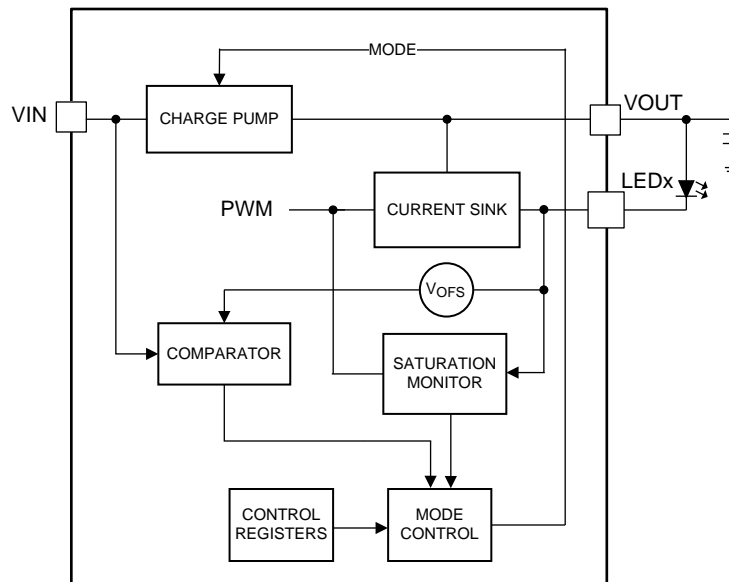

The charge pump is controlled with two CP_MODE bits in the MISC register (address 2Fh). When both of the bits are low, the charge pump is disabled, and output voltage is pulled down as described in [Output Discharge](#). The charge pump can be forced to the bypass mode, so the battery voltage is connected directly to the current source; in 1.5x mode the output voltage is boosted to 4.5 V. In automatic mode, the charge-pump operation mode is determined by saturation of the constant-current drivers described in [LED Forward Voltage Monitoring](#).

8.3.2.6 LED Forward Voltage Monitoring

When the charge-pump automatic-mode selection is enabled, voltages on the LED current sinks LED0 to LED8 are monitored. If the current sinks do not have enough headroom, the charge pump gain is set to 1.5x and remains in 1.5x mode until one of the following occurs:

- The LP5569 device enters the SHUTDOWN state and goes through the INITIALIZATION or STARTUP state.
- The charge-pump mode is forced to 1x mode via the MISC register.
- The LP5569 device exits power save when the charge pump is in automatic mode (CP_MODE bits = 3h).

A current-sink saturation monitor is selectable to one of four fixed voltage thresholds. The charge-pump gain is set to 1x when the battery voltage is high enough to supply all LEDs. Note: forward-voltage monitoring is disabled when the LEDx_CONTROL (addresses 07h–0Fh) register EXTERNAL_POWERx bit = 1.

Figure 18. Forward-Voltage-Monitoring and Gain-Control Block

8.3.3 Energy Efficiency

8.3.3.1 LED Powering

The red LED (R) element of an RGB LED typically has a forward voltage of about 2 V. These LEDs can be powered directly from the input voltage because battery voltage is typically high enough to drive red LEDs over the whole operating voltage range. This allows driving of three RGB LEDs with good efficiency because the red LEDs do not load the charge pump. When the LEDx_CONTROL (address 07h–0Fh) register EXTERNAL_POWERx bit = 1, the LEDx output is configured for external supply, and forward-voltage monitoring is disabled.

8.3.4 Automatic Power-Save Mode

When the LED outputs are not active, the LP5569 device is able to enter the power-save mode automatically, thus lowering idle-current consumption down to 10 μ A (typical). Automatic power-save mode is enabled when the MISC register (address 2Fh) POWERSAVE_EN bit = 1. Almost all analog blocks are powered down in power save, if an external clock signal is used. The charge pump enters the weak 1 \times mode using a passive current-limited keep-alive switch, which keeps the output voltage at the battery level to reduce output-voltage transients.

During program execution, the LP5569 device can enter power save if there is no PWM activity in any of the LED driver outputs. To prevent short power-save sequences during program execution, the device has an instruction look-ahead filter. In power-save mode, program execution continues without interruption. When an instruction that requires PWM activity is executed, a fast internal start-up sequence is started automatically.

8.3.5 Protection Features

8.3.5.1 Thermal Shutdown (TSD)

The LP5569 device implements a thermal shutdown mechanism to protect the device from damage due to overheating. When the junction temperature rises to 150°C (typical), the device switches into shutdown mode. The LP5569 device releases thermal shutdown when the junction temperature of the device decreases to 130°C (typical).

Thermal shutdown is most often triggered by self-heating, which occurs when there is excessive power dissipation in the device and/or insufficient thermal dissipation. LP5569 power dissipation increases with increased output current and input voltage. When self-heating brings on thermal shutdown, thermal cycling is the typical result. Thermal cycling is the repeating process where the part self-heats, enters thermal shutdown (where internal power dissipation is practically zero), cools, turns on, and then heats up again to the thermal shutdown threshold. Thermal cycling is recognized by a pulsing output voltage and can be stopped by reducing the internal power dissipation (reduce input voltage and/or output current) or the ambient temperature. If thermal cycling occurs under desired operating conditions, thermal dissipation performance must be improved to accommodate the power dissipation of the LP5569 device. The QFN package is designed to have excellent thermal properties that, when soldered to a PCB designed to aid thermal dissipation, allows the LP5569 device to operate under very demanding power-dissipation conditions.

8.3.5.2 Undervoltage Lockout (UVLO)

The LP5569 device has an internal comparator that monitors the voltage at VIN. If the input voltage drops to 2.2 V (nominal), undervoltage is detected, the LED outputs and the charge pump shut down, and the corresponding fault bit is set in the fault register. Hysteresis is implemented for the threshold level to avoid continuous triggering of a fault when the threshold is reached. If the input voltage rises above 2.3 V (nominal), the LP5569 device resumes normal operation.

8.3.5.3 Power-On Reset (POR)

The LP5569 device has internal comparators that monitor the voltages at VIN and V1P8. When V_{VIN} is below 2.2 V or V1P8 is below 1.3 V, reset is active and the LP5569 device is in the DISABLED state.

8.3.5.4 LED Fault Detection

The LP5569 device contains both open-LED and shorted-LED fault detection. These fault detections are designed to be used in production-level testing and not normal operation. For the fault flags to operate, they must be enabled via the MISC2 register (address 33h) LED_OPEN_TEST and LED_SHORT_TEST bits. The fault flags are shared by both open-LED and shorted-LED tests so only one can be enabled at a time. The default LED-fault status is ready in the LED_FAULT1 and LED_FAULT2 registers (addresses 81h and 82h). The following sections detail the proper procedure for reading back open and short faults in the LED strings.

8.3.5.4.1 Open LED

The LP5569 device features one fault flag per LED, indicating one or more of the active low-voltage LED strings are open. An open in a low-voltage LED string is flagged if the voltage at the input to any active low-voltage current sink goes below the `drv_headroom[1:0]` setting in the MISC2 register. The procedure for detecting an open-LED fault is:

1. Set the LP5569 device in the STANDBY state.
2. Configure the charge pump in the 1.5x mode.
3. Set the LED_OPEN_TEST bit = 1 in the MISC2 register (address 33h).
4. Set the chip_en bit = 1 in the CONTROL register (address 0h) with the LP5569 device in the NORMAL state.
5. Wait at least 500 μ s.
6. Enable all LEDs, and set all LEDs to 100% brightness.
7. Wait at least 500 μ s.
8. Check the fault status of the LED_FAULT1 and LED_FAULT2 registers.
9. Set the LED_OPEN_TEST bit = 0 in the MISC2 register (address 33h).
10. Set all LEDs to 0% brightness.

8.3.5.4.2 Shorted LED

The LP5569 device features one fault flag per LED, indicating when any active LED is shorted (anode to cathode). During the LED short test, the charge pump is forced to the 1x mode. A short in the LED is determined when the LED voltage ($V_{IN} - V_{LEDx}$) falls below 1 V. The procedure for detecting a shorted-LED fault is:

1. Set the LP5569 device in the STANDBY state.
2. Configure the charge pump in the 1x mode, set LED PWM (0x16–0x1E) and LED current (0x22–0x2A) to maximum value, depending on the LED channel being tested.

3. Set the chip_en bit in the CONFIG register = 1 and the LP5569 device to the NORMAL state.
4. Wait at least 500 μ s.
5. Enable all LEDs, and set brightness to 100%.
6. Set the LED_SHORT_TEST bit = 1 in the MISC2 register (address 33h).
7. Wait at least 500 μ s.
8. Check the fault status of the LED Fault1 and LED Fault2 registers.
9. Set the LED_SHORT_TEST bit = 0 in in the MISC2 register (address 33h).
10. Set all LEDs to 0% brightness.

8.3.6 Clock Generation and Synchronization

The LP5569 device can generate a 32-kHz clock signal and use it for synchronizing multiple devices. The CLK pin is configured as an input by default. When the EN_CLK_OUT bit = 1 in the IO_CONTROL register (address 3Dh) the LP5569 device drives the CLK pin using its 32-kHz oscillator.

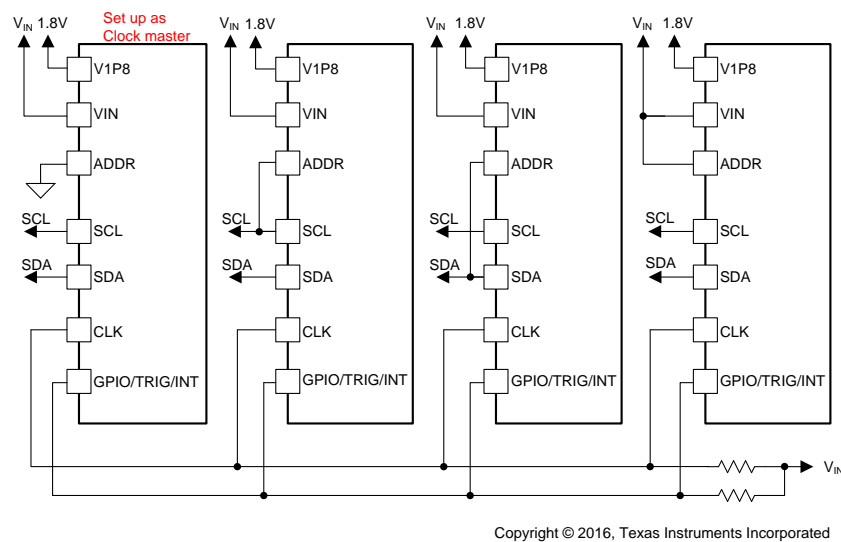

Figure 19. Synchronizing Multiple Devices Using the Clock Generator

8.3.7 GPIO/TRIG/INT Multifunctional I/O

The GPIO/TRIG/INT pin is configured by the GPIO_CONFIG bits in the IO_CONTROL register (address 3Dh). The default configuration for this pin is the INT function.

8.4 Device Functional Modes

8.4.1 Modes Of Operation

CP_LED_STARTUP: LED drivers are enabled. The device enters NORMAL after 300 μ s (typical).

CP_ON: Charge pump is enabled per CP_MODE bits, and charge-pump output voltage is within regulation after 300 μ s (typical).

CP_WAKEUP After the power-save condition is no longer met, the device enters the CP_WAKEUP state. The device enters CP_LED_STARTUP after 100 μ s (typical).

DISABLED: The device enters this state when logic receives POR or the EN/PWM pin is low for longer than 15 ms (typical). The internal logic is disabled in this state to minimize power consumption. The mode changes to INITIALIZATION when a rising edge has been detected in the EN/PWM pin and TSD is inactive.

INITIALIZATION: This state duration is 2 ms (typical). The device enters the OTP_READ–SRAM_INIT state if V_{VIN} is above the V_{UVLO} level, and the temperature is below TSD. If V_{VIN} is below V_{UVLO} or TSD is active, the device remains in INITIALIZATION unless EN/PWM is low for 15 ms (typical), then the device enters the DISABLED mode.

INTERNAL POWER SHUTDOWN: In INTERNAL POWER SHUTDOWN mode, the internal LDO is shutdown.

NORMAL: After startup has been completed the device enters the NORMAL mode. Users can drive LEDs and execute programs in this mode.

OTP_READ - SRAM_INIT: The OTP_READ mode is followed by SRAM_INIT, which initializes SRAM. When initialization is complete, the device enters the STANDBY state. If V_{IN} is below V_{UVLO} while in this state, the device returns to INITIALIZATION.

POWER SAVE: In POWER SAVE mode, analog blocks are disabled to minimize power consumption. After the power-save condition is no longer met, the device exits the POWER SAVE mode. See [Automatic Power-Save Mode](#) section for further information.

SHUTDOWN: During shutdown, the charge-pump and LED drivers are disabled. The device enters the shutdown state if disabled ($chip_en = 0$) or if a TSD fault is active. The device enters STANDBY after 1 ms (typical).

STANDBY: The STANDBY mode is a low-power-consumption mode and is entered if the register bit $chip_en$ is zero and Reset is not active. Register and SRAM access is available via I²C.

START-UP: During a fault condition, device operation is halted, and the device waits in STARTUP mode until no faults are present. UVLO detection returns the device to STARTUP from all states with the exception of STANDBY, INITIALIZATION, and OTP_READ - SRAM_INIT.

Device Functional Modes (continued)

Figure 20. LP5569 Function State Machine

8.5 Programming

8.5.1 I²C Interface

The I²C-compatible two-wire serial interface provides access to the programmable functions and registers on the device. This protocol uses a two-wire interface for bidirectional communications between the devices connected to the bus. The two interface lines are the serial data line (SDA) and the serial clock line (SCL). Every device on the bus is assigned a unique address and acts as either a master or a slave depending on whether it generates or receives the serial clock, SCL. The SCL and SDA lines should each have a pullup resistor placed somewhere on the line and remain HIGH even when the bus is idle. Note: the CLK pin is not used for serial bus data transfer.

8.5.1.1 Data Validity

The data on SDA line must be stable during the HIGH period of the clock signal (SCL). In other words, state of the data line can only be changed when clock signal is LOW.

Figure 21. Data Validity Diagram

8.5.1.2 Start and Stop Conditions

START and STOP conditions classify the beginning and the end of the data transfer session. A START condition is defined as the SDA signal transitioning from HIGH to LOW while SCL line is HIGH. A STOP condition is defined as the SDA transitioning from LOW to HIGH while SCL is HIGH. The bus master always generates START and STOP conditions. The bus is considered to be busy after a START condition and free after a STOP condition. During data transmission, the bus master can generate repeated START conditions. First START and repeated START conditions are functionally equivalent.

8.5.1.3 Transferring Data

Every byte put on the SDA line must be eight bits long, with the most significant bit (MSB) being transferred first. Each byte of data must be followed by an acknowledge bit. The acknowledge-related clock pulse is generated by the master. The master releases the SDA line (HIGH) during the acknowledge clock pulse. The LP5569 device pulls down the SDA line during the ninth clock pulse, signifying an acknowledge. The LP5569 device generates an acknowledge after each byte has been received.

There is one exception to the *acknowledge after every byte* rule. When the master is the receiver, it must indicate to the transmitter an end of data by not-acknowledging (*negative acknowledge*) the last byte clocked out of the slave. This *negative acknowledge* still includes the acknowledge clock pulse (generated by the master), but the SDA line is not pulled down.

After the START condition, the bus master sends a device address. This address is seven bits long followed by an eighth bit which is a data direction bit (READ or WRITE). For the eighth bit, a 0 indicates a WRITE, and a 1 indicates a READ. The second byte selects the register to which the data is to be written. The third byte contains data to write to the selected register.

8.5.1.4 I²C Slave Addressing

The LP5569 slave address is defined by connecting GND, SCL, SDA, or VIN to the ADDR pin. A total of four slave addresses can be realized by combinations when GND, SCL, SDA, or VIN is connected to the ADDR pin (see [Table 2](#)).

The LP5569 device is available in two versions (LP5569 and LP5569A). Each version has four possible address settings, which allows up to eight devices sharing the same I²C bus as shown in [Table 2](#). Values are in 7-bit slave ID format. The LP5569 device responds to slave address 40h regardless of the setting of the ADDR pin and device version. Global writes to address 40h can be used for configuring all devices simultaneously. The LP5569 device supports global read using slave address 40h; however, the data read is only valid if all LP5569 devices on the I²C bus contain the same value in the register read.

Table 2. LP5569 Slave-Address Combinations

SLAVE ID	VERSION	ADDR
32h and 40h		GND
33h and 40h		SCL
34h and 40h		SDA
35h and 40h		VIN
42h and 40h	A	GND
43h and 40h	A	SCL
44h and 40h	A	SDA
45h and 40h	A	VIN

Figure 22. LP5569 Chip Address

8.5.1.5 Control Register Write Cycle

1. The master device generates a start condition.
2. The master device sends the slave address (7 bits) and the data direction bit ($R/\overline{W} = 0$).
3. The slave device sends an acknowledge signal if the slave address is correct.
4. The master device sends the control register address (8 bits).
5. The slave device sends an acknowledge signal.
6. The master device sends the data byte to be written to the addressed register.
7. The slave device sends an acknowledge signal.
8. If the master device sends further data bytes, the control register address of the slave is incremented by 1 after the acknowledge signal. In order to reduce program load time, the LP5569 device supports address auto incrementation. The register address is incremented after each 8 data bits. For example, the whole program memory page can be written in one serial-bus write sequence.
9. The write cycle ends when the master device creates a stop condition.

Figure 23. Write Cycle (W = Write; SDA = 0)

8.5.1.6 Control Register Read Cycle

1. The master device generates a start condition.
2. The master device sends the slave address (7 bits) and the data direction bit ($R/\overline{W} = 0$).
3. The slave device sends an acknowledge signal if the slave address is correct.
4. The master device sends the control register address (8 bits).
5. The slave device sends an acknowledge signal.

6. The master device generates a repeated-start condition.
7. The master device sends the slave address (7 bits) and the data direction bit ($R/\overline{W} = 1$).
8. The slave device sends an acknowledge signal if the slave address is correct.
9. The slave device sends the data byte from the addressed register.
10. If the master device sends an acknowledge signal, the control register address is incremented by 1. The slave device sends the data byte from the addressed register.
11. The read cycle ends when the master device does not generate an acknowledge signal after a data byte and generates a stop condition.

Figure 24. Read Cycle (R = Read; SDA = 1)

8.5.1.7 Auto-Increment Feature

The auto-increment feature allows writing several consecutive registers within one transmission. Every time an 8-bit word is sent to the LP5569 device, the internal address index counter is incremented by 1, and the next register is written. The auto-increment feature is enabled by default and can be disabled by setting the EN_AUTO_INCR bit = 0 in the MISC register (address 2Fh).

8.5.2 Execution Engine Programming

The LP5569 device provides flexibility and programmability for dimming and sequencing control. Each LED can be controlled directly and independently through the serial bus, or LED drivers can be grouped together for pre-programmed flashing patterns.

The LP5569 device has three independent program execution engines, so it is possible to form three independently programmable LED banks. LED drivers can be grouped based on their function so that, for example, the first bank of drivers can be assigned to the keypad illumination, the second bank to the *funlights*, and the third group to the indicator LED(s). Each bank can contain 1 to 9 LED driver outputs. Instructions for program execution engines are stored in the program memory. The total amount of the program memory is 255 instructions, and the user can allocate the instructions as required by the engines; however, a single engine can only allocate up to ½ the memory (128 instructions).

8.5.2.1 SRAM Memory

The LP5569 device has internal SRAM for the three LED engines. SRAM can contain up to 255 16-bit instructions (addresses 0 through 254) with a maximum size of 128 16-bit instructions for a single engine. SRAM memory address 255 is reserved and must not be allocated to any LED engine. Memory allocation among the three LED engines is done dynamically, so that each LED engine has a separate start address and program counter (PC) that are set in the ENGINE_x_PROG_START registers (addresses 4Bh, 4Ch, 4Dh) and ENGINE_x_PC registers (addresses 30h, 31h, 32h). This allows flexible memory allocation among the LED engines, and multiple engines can recall the same memory address. The program counter uses relative memory addressing; when the PC is zero the engine is executing an instruction at its start address.

The SRAM is loaded via the I²C interface in 33-byte-length pages. The first byte contains the program-memory-page-select (address 4Fh) followed by up to 32 bytes containing compiled program execution engine instructions (address 50h thru 6Fh). Engines must be set to load the program mode (register 01h) before writing the SRAM.

8.5.2.2 Variables

The LP5569 device has four LED engine variables which are divided into local and global variables. Variables A and B are engine-specific local variables and each of the three engines has separate A and B variables, so there is a total of six A and B variables. Variable A can be read and written via I²C registers 42h–44h. Local variable B is not available via I²C and can only be accessed by the LED engine. Variables C and D are global variables which are shared by all three LED engines. Global variable C is not available via I²C and can only be accessed by the LED engines. The D variable can be read and written via I²C register 3Eh. Variables are referenced to instructions with 2 bits, see [Table 3](#) for details. Note that some instructions (ld, add, sub) can use only variables A, B, and C as target variables.

Table 3. LED Engine Variables

VARIABLE	BITS	LOCAL/GLOBAL
A	00	Local
B	01	Local
C	10	Global
D	11	Global

8.5.2.3 Instruction Set

The LP5569 device has three independent programmable execution engines. All the program execution engines have their own program memory block allocated by the user. The maximum program size for any one engine is limited to 128 locations. At least one engine must be in the load-program mode with the engine-busy bit cleared before writing to any program memory address. Program execution is clocked with a 32.768-kHz clock. Instruction execution takes sixteen clock cycles (488 μs). This applies also to ramp and wait instructions where execution time is a multiple of 488 μs. This clock can be generated internally or an external clock can be supplied to the CLK pin. Using an external clock enables synchronization of LED timing to the external clock signal and is also more power-efficient. The supported instruction set is listed in [Table 4](#) through [Table 6](#). The LP5569 device is fully compatible with the LP5523 instruction set. A command compiler is available for easy sequence programming. With the command compiler it is possible to write sequences with simple ASCII commands, which are then converted to binary or hex format.

Table 4. LED Driver Instructions

INSTRUCTION	USAGE	COMPILER EXAMPLE
ramp ⁽¹⁾	Generate a programmable PWM ramp to mapped LED driver(s) from the current value to a new value in steps of +1 or –1 with programmed step time.	<i>ramp 0.6, 255; ramp to full scale in 0.6 s</i>
ramp ⁽²⁾	ramp var1, prescale, var2 var1 is a variable (ra, rb, rc, rd); prescale is a boolean constant (pre = 0 or pre = 1); Var2 is a variable (ra, rb, rc, rd). Output PWM with increasing or decreasing duty cycle.	<i>ld ra, 31 ld rb, 255 ramp ra, pre=0, +rb; ramp up to full scale over 3.9 s.</i>
set_pwm ⁽¹⁾	Set PWM or current value to mapped LED driver(s), effective immediately.	<i>set_pwm 128; set duty cycle to 50%.</i>
set_pwm ⁽²⁾	set_pwm var1 Var1 is a variable (ra, rb, rc, rd). Generate a continuous PWM output.	<i>ld rc, 128; set_pwm rc; set PWM duty cycle to 50%.</i>
wait	Wait for a given time. Time span is from 0.488 ms to 484 ms.	<i>wait 0.4; wait for 0.4 s; wait for 0.4 s</i>

(1) This opcode is used with numerical operands.

(2) This opcode is used with variables.

Table 5. LED Mapping Instructions

INSTRUCTION ⁽¹⁾	ACT ⁽²⁾	USAGE	COMPILER EXAMPLE
load_start		Define the LED mapping-table start address in SRAM.	<i>load_start 01h</i> ; starting address at 01h
map_start	x	Define the LED mapping-table start address in SRAM and set that address active.	<i>map_start 01h</i> ; starting address at 01h
load_end		Define the last address of the LED mapping table in SRAM.	<i>load_end 03h</i> ; last address at 03h
map_sel	x	Connect one LED driver to the LED engine.	<i>map_sel 0</i> ; select LED0 as output
map_clr	x	Clear the LED driver mappings in an engine	<i>map_clr</i>
map_next	x	Select the next address in the LED mapping table and set that address active.	<i>map_next</i>
map_prev	x	Select the previous address in the LED mapping table and set that address active.	<i>map_prev</i>
load_next		Move the mapping-table pointer to the next address.	<i>load_next</i>
load_prev		Move the mapping-table pointer to the previous address.	<i>load_prev</i>
load_addr		Set the mapping-table pointer to the assigned address.	<i>load_addr 02h</i> ; set pointer to 02h
map_addr	x	Set the mapping-table pointer to the assigned address and set that address active.	<i>map_addr 02h</i> ; set mapping to 02h

(1) These instructions are compatible with the LP5523 and LP55231 mux_* LED mapping instructions.

(2) x - The instruction activates LED mapping to the driver when the instruction is executed.

Table 6. Branch Instructions

INSTRUCTION	USAGE	COMPILER EXAMPLE
rst	Reset program counter to zero.	Reset
branch⁽¹⁾	Branch to address. The number of loops can be set to a value or do an infinite loop.	<i>branch 20, loop1</i> ; do 20 loops to loop1 label
branch⁽²⁾	Branch to address. The loop count can be one of four variables A, B, C, or D.	<i>ld ra, 20 branch ra, loop1</i> ; do 20 loops to loop1 label
int	Send an interrupt to the host system by pulling the GPIO/TRIG/INT pin low.	<i>int</i>
end	End program execution and reset the program counter to zero. Can also set GPIO/TRIG/INT pin high and/or reset mapped LED PWM and engine LED mapping.	<i>end</i> ; end and reset LEDs.
trigger	Wait or send trigger. The trigger can be sent or received from an external pin or another engine.	<i>trigger w{e}</i> ; wait for external trigger
trig_clear⁽³⁾	Clear pending triggers.	<i>trig_clear</i>
jne	Jump if not equal. A != B	Jump to loop1 if A != B: <i>jne ra, rb, loop1</i>
jl	Jump if less. A < B	Jump to loop1 if A < B: <i>jl ra, rb, loop1</i>
jge	Jump if greater or equal. A ≥ B	Jump to loop1 if A ≥ B: <i>jge ra, rb, loop1</i>
je	Jump if equal. A = B	Jump to loop1 if A = B: <i>je ra, rb, loop1</i>

(1) This opcode is used with numerical operands.

(2) This opcode is used with variables.

(3) This is a new instruction, not available in LP5523 or LP55231

Table 7. Data Transfer and Arithmetic

INSTRUCTION	USAGE	COMPILER EXAMPLE
ld ⁽¹⁾	Assign a value to a variable.	<i>ld ra, 33</i> ; load value 33h to local variable A
add ⁽¹⁾	Add the 8-bit value to the variable value.	<i>add ra, 11</i> ; add value 11h to local variable A
add ⁽²⁾	Add the value of variable 3 (global variable D) to the value of variable 2 (global variable C) and store the result in variable 1 (local variable A).	<i>add ra, rc, rd</i> ; add the value in rd to rc and store in ra
sub ⁽¹⁾	Subtract the 8-bit value from the variable value.	<i>sub ra, 11</i> ; subtract value 11h from local variable A
sub ⁽²⁾	Subtract the value of variable 3 (global variable D) from the value of variable 2 (global variable C) and store the result in variable 1 (local variable A).	<i>sub ra, rc, rd</i> ; subtract the value in rd from rc and store in ra

- (2) This opcode is used with variables.

8.5.2.4.1 Ramp

This is the instruction useful for smoothly changing from one PWM value into another PWM value on the LED0 to LED8 outputs—in other words, generating ramps with a negative or positive slope. The LP5569 device allows the programming of very fast and very slow ramps using only a single instruction. Full ramp 0 to 255 ramp time ranges from 124 ms to 4 s.

The ramp instruction generates a PWM ramp, using the effective PWM value as a starting value. At each ramp step the output is incremented or decremented by 1, unless the number of increments is 0. The time span for one ramp step is defined with the prescale bit [14] and step-time bits [13:9]. The ramp instruction controls the eight most-significant bits (MSB) of the PWM values and the remaining bits are interpolated as ramp mid-values internally for smoother transition.

Prescale = 0 sets a 0.49-ms cycle time and prescale = 1 sets a 15.6-ms cycle time; so the minimum time span for one step is 0.49 ms (prescale × step time span = 0.49 ms × 1) and the maximum time span is 15.6 ms × 31 = 484 ms/step. If all the step-time bits [13:9] are set to zero, the output value is incremented or decremented during one prescale on the whole time cycle.

The number-of-increments value defines how many steps are taken during one ramp instruction: the increment maximum value is 255, which corresponds to an increment from zero value to the maximum value. If PWM reaches the minimum or maximum value (0 or 255) during the ramp instruction, the ramp instruction is executed to the end regardless of saturation. This enables ramp instruction to be used as a combined ramp-and-wait instruction. Note: the ramp instruction is a wait instruction when the increment bits [7:0] are set to zero.

Programming ramps with variables is very similar to programming ramps with numerical operands. The only difference is that step time and number of increments are captured from variable registers when the instruction execution is started. If the variables are updated after starting the instruction execution, it has no effect on instruction execution. Again, at each ramp step the output is incremented or decremented by 1 unless the step time is 0 or the number of increments is 0. The time span for one step is defined with the prescale and step-time bits. The step time is defined with variable A, B, C, or D. Variable A is set by an I²C write to the engine 1, 2, or 3 variable A register or the *ld* instruction, variables B and C are set with the *ld* instruction, and variable D is set by an I²C write to the variable D register.

Setting the EXP_EN bit of registers 07h–0Fh high or low sets the exponential (1) or linear ramp (0). By using the exponential ramp setting, the visual effect appears like a linear ramp to the human eye.

Table 9. Ramp Instructions

INST.	Bit [15]	Bit [14]	Bit [13]	Bit [12]	Bit [11]	Bit [10]	Bit [9]	Bit [8]	Bit [7]	Bit [6]	Bit [5]	Bit [4]	Bit [3]	Bit [2]	Bit [1]	Bit [0]	
ramp ⁽¹⁾	0	pre-scale	step time					sign	no. of increments								
ramp ⁽¹⁾	1	0	0	0	0	1	0	0	0	0	pre-scale	sign	step-time variable	no.-of-increments variable			

(1) Compatible with LP5523 and LP55231

PARAMETER NAME	NUMERIC OR VARIABLE	VALUE (d)	DESCRIPTION
prescale	Numeric	0	32.7 kHz / 16 ≥ 0.488 ms cycle time
		1	32.7 kHz / 512 ≥ 15.625 ms cycle time
sign	Numeric	0	Increase PWM output
		1	Decrease PWM output
step time	Numeric	1–31	One ramp increment done is in step time × prescale. Value in the variable A, B, C, or D must be from 1 to 31 for correct operation.
	Variable	0–3	
no. of increments	Numeric	0–255	The number of ramp cycles. Variables A to D as input.
	Variable	0–3	

8.5.2.4.2 Ramp Instruction Application Example

An example of generating a 1.5-s ramp from PWM value 140 (approximately 55%) to 148 (approximately 58%). The ramp instruction uses relative values, so in this example we must ramp 8 steps up, as shown in Figure 25. The parameters for the RAMP instruction are:

- Positive ramp → sign = 0 (increase by 1)
- Step from 140 to 148 → no. of increments = 8
- Ramp time 1.5 s → 1.5 s / 8 steps = 187.5 ms/step
- Prescale = 1 → 15.625 ms cycle time
- 187.5 ms / 15.625 ms = 12 → step time = 12

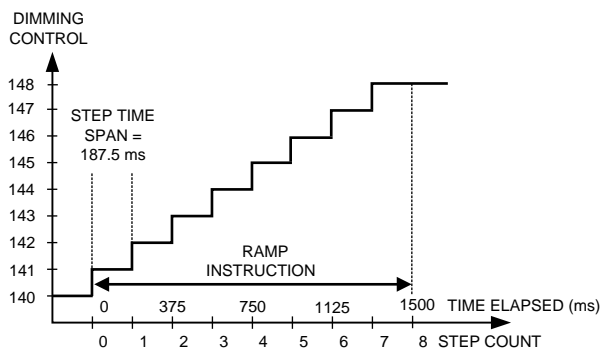

Figure 25. Example of Ramp Instruction

8.5.2.4.3 Set_PWM

This instruction is used for setting the PWM value on outputs LED0 to LED8 without any ramps. Set the PWM output value from 0 to 255 with PWM value bits [7:0]. Instruction execution takes 16 32-kHz clock cycles (= 488 μ s).

NAME	VALUE (d)	DESCRIPTION
PWM value ⁽¹⁾	0–255	PWM output duty cycle 0–100%
variable ⁽²⁾	0–3	0 = local variable A 1 = local variable B 2 = global variable C 3 = global variable D

(1) Valid for numerical operands

(2) Valid for variables

8.5.2.4.4 Wait

When a *wait* instruction is executed, the engine is set in wait status, and the PWM values on the outputs are frozen. Note: A *wait* instruction with prescale and time = 0 is invalid and is executed as *rst*.

NAME	VALUE (d)	DESCRIPTION
prescale	0	Divide master clock (32.7 kHz) by 16 which means 0.488 ms cycle time.
	1	Divide master clock (32.7 kHz) by 512 which means 15.625 ms cycle time.
time	1–31	Total wait time is = (time) \times (prescale). Maximum 484 ms, minimum 0.488 ms.

8.5.2.5 LED Mapping Instructions

These instructions define the engine-to-LED mapping. The mapping information is stored in a table, which is stored in the lower half of SRAM (program memory of the LP5569 device). The LP5569 device has three program execution engines which can be mapped to nine LED drivers. One engine can control one or multiple LED drivers. Execution engine 1 has priority over execution engines 2 and 3, with execution engine 2 having priority over execution engine 3. If an LED is mapped to more than one execution engine, the higher-priority engine controls the LED.

LED mapping instructions can be divided to two groups:

- Instructions that activate LED mapping to a certain row of the table (*map_* instructions).
- Instructions that DO NOT activate the actual LED mapping but just shift the mapping-table pointer (*load_* instructions).

Activating instructions are *map_start*, *map_sel*, *map_clr*, *map_next*, *map_prev* and *map_addr*. Instructions *load_start*, *load_end*, *load_next*, *load_prev* and *load_addr* do not activate the LED mapping. Mapping table and master fader bits can be read from I²C registers 70h–75h but are written only via engine instructions.

When an engine is actively mapped to the LEDs, the engine takes over the LED PWM control, and PWM control registers have no effect. Register control is returned when the engine is mapped to another LED. See [Figure 26](#) for a simplified diagram of LED-engine data flow. The engine does not push a new PWM value to the LED driver output before the *set_pwm* or *ramp* instruction is executed. If the mapping has been released from an LED, the value in the PWM register still controls the LED brightness, and the PWM register value remains in the last engine state.

Actual PWM control resolution of the LED engines is 12 bits, but only the 8 highest bits are visible in the I²C registers. Also, engine commands use the 8 high bits for control, and the 4 low bits are used for smoother ramps.

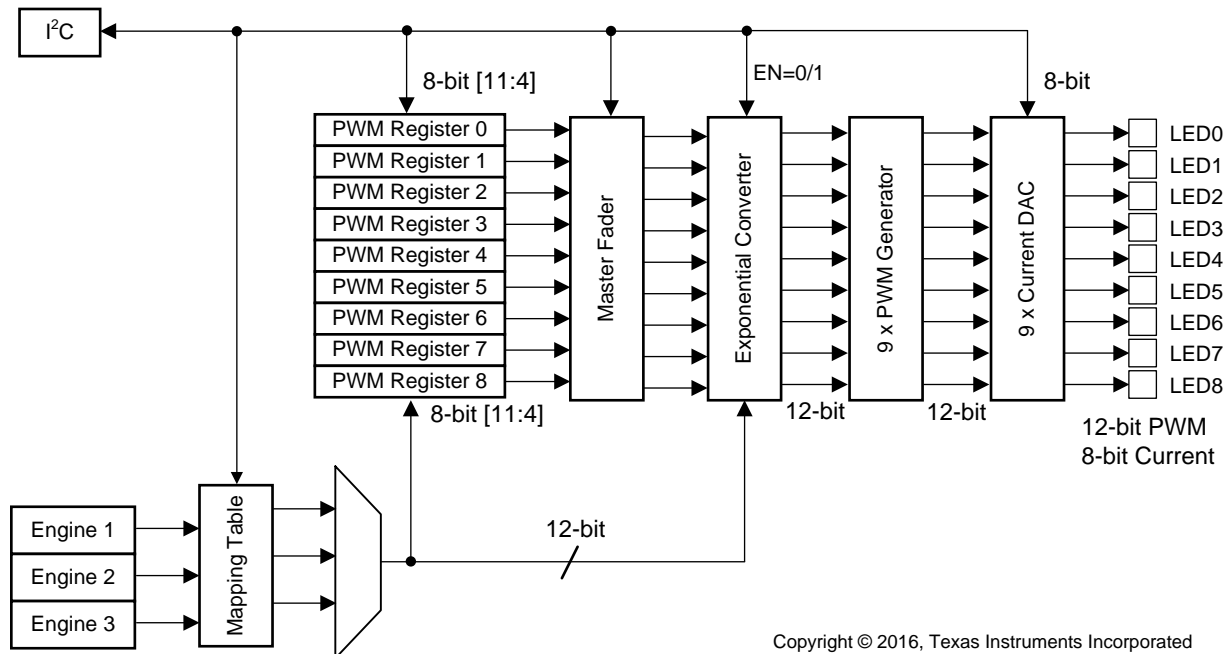

Figure 26. LED Data Flow

All LED mapping instructions use the SRAM bit to LEDx pin mapping as shown in Table 10.

Table 10. LED Mapping Bits in SRAM

	Bit [15]	Bit [14]	Bit [13]	Bit [12]	Bit [11]	Bit [10]	Bit [9]	Bit [8]	Bit[7]	Bit[6]	Bit[5]	Bit[4]	Bit[3]	Bit[2]	Bit[1]	Bit 0
LED mapping table in SRAM	—	—	—	—	—	—	0	LED8	LED 7	LED6	LED 5	LED4	LED3	LED2	LED1	LED0

Bit[9] is to enable master fader control by the engine. If this bit is set to 1 in engine 1, then master fader 1 is enabled.

Table 11. LP5569 LED Mapping Instructions

INST. (1)	Bit [15]	Bit [14]	Bit [13]	Bit [12]	Bit [11]	Bit [10]	Bit [9]	Bit [8]	Bit [7]	Bit [6]	Bit [5]	Bit [4]	Bit [3]	Bit [2]	Bit [1]	Bit [0]
load_start	1	0	0	1	1	1	1	0	0	SRAM addresses 0–127 ⁽²⁾						
map_start	1	0	0	1	1	1	0	0	0	SRAM addresses 0–127 ⁽²⁾						
load_end	1	0	0	1	1	1	0	0	1	SRAM addresses 0–127 ⁽²⁾						
map_sel	1	0	0	1	1	1	0	1	0	LED select ⁽³⁾						
map_clr	1	0	0	1	1	1	0	1	0	0	0	0	0	0	0	0
map_next	1	0	0	1	1	1	0	1	1	0	0	0	0	0	0	0
map_prev	1	0	0	1	1	1	0	1	1	1	0	0	0	0	0	0
load_next	1	0	0	1	1	1	0	1	1	0	0	0	0	0	0	1
load_prev	1	0	0	1	1	1	0	1	1	1	0	0	0	0	0	1
load_addr	1	0	0	1	1	1	1	1	0	SRAM addresses 0–127 ⁽²⁾						
map_addr	1	0	0	1	1	1	1	1	1	SRAM addresses 0–127 ⁽²⁾						

- (1) These instructions are compatible with LP5523 and LP55231 mux_* LED mapping instructions.
- (2) Absolute address
- (3) Only values 1 through 9 are valid, any other value results in no LED driver selected.

8.5.2.5.1 LOAD_START and LOAD_END

The *load_start* and *load_end* instructions define the mapping table locations in SRAM.

NAME	VALUE (d)	DESCRIPTION
SRAM address	0–127	Mapping table start or end address restricted to lower half of memory.

8.5.2.5.2 MAP_START

The *map_start* instruction defines the mapping table start address in the memory, and the first row of the table is activated (mapped) at the same time.

NAME	VALUE (d)	DESCRIPTION
SRAM address	0–127	Mapping table start address restricted to lower half of memory.

8.5.2.5.3 MAP_SEL

With the *map_sel* instruction one, and only one, LED driver can be connected to a program execution engine. Connecting multiple LEDs to one engine is done with the mapping table. After the mapping has been released from an LED, the PWM register value still controls the LED brightness.

NAME	VALUE (d)	DESCRIPTION
LED select	0–127	0 = no drivers selected
		1 = LED1 selected
		2 = LED1 selected
		...
		9 = LED9 selected
		10–127 = no drivers selected

8.5.2.5.4 MAP_CLR

The *map_clr* instruction clears engine-to-driver mapping. After the mapping has been released from an LED, the PWM register value still controls the LED brightness.

8.5.2.5.5 MAP_NEXT

This instruction sets the next row active in the mapping table each time it is called. For example, if the second row is active at this moment, after the *map_next* instruction call the third row is active. If the mapping table end address is reached, activation rolls to the mapping-table start address the next time when the *map_next* instruction is called. The engine does not push a new PWM value to the LED driver output before the *set_pwm* or *ramp* instruction is executed. If the mapping has been released from an LED, the value in the PWM register still controls the LED brightness.

8.5.2.5.6 LOAD_NEXT

Similar to the *map_next* instruction with the exception that no mapping is set. The index pointer is set to point to the next row and the engine-to-LED-driver connection is not updated.

8.5.2.5.7 MAP_PREV

This instruction sets the previous row active in the mapping table each time it is called. For example, if the third row is active at this moment, after the *map_prev* instruction call the second row is active. If the mapping table start address is reached, activation rolls to the mapping table end address next time the *map_prev* instruction is called. The engine does not push a new PWM value to the LED driver output before the *set_pwm* or *ramp* instruction is executed. If the mapping has been released from an LED, the value in the PWM register still controls the LED brightness.

8.5.2.5.8 LOAD_PREV

Similar to the *map_prev* instruction with the exception that no mapping is set. The index pointer is set to point to the previous row and the engine-to-LED-driver connection is not updated.

8.5.2.5.9 MAP_ADDR

The *map_addr* instruction sets the index pointer to point to the mapping table row defined by bits [6:0] and sets the row active. The engine does not push a new PWM value to the LED driver output before the *set_pwm* or *ramp* instruction is executed. If the mapping has been released from an LED, the value in the PWM register still controls the LED brightness.

NAME	VALUE (d)	DESCRIPTION
SRAM address	0–127	SRAM address containing mapping data restricted to lower half of memory.

8.5.2.5.10 LOAD_ADDR

The *load_addr* instruction sets the index pointer to point to the mapping table row defined by bits [6:0], but the row is not set active.

NAME	VALUE (d)	DESCRIPTION
SRAM address	0–127	SRAM address containing mapping data restricted to lower half of memory.

8.5.2.6 Branch Instructions

8.5.2.6.1 BRANCH

The branch instruction is provided for repeating a portion of the program code several times. The branch instruction loads a step number value to the program counter. A loop count parameter defines how many times the instructions inside the loop are repeated. The step number is loaded into the PC when the instruction is executed. The PC is relative to the `ENGINEx_PROG_START` register setting. The LP5569 device supports nested looping, that is, a loop inside a loop. The number of nested loops is not limited. The instruction takes 16 32-kHz clock cycles.

Table 12. LP5569 Branch Instructions

INST.	Bit [15]	Bit [14]	Bit [13]	Bit [12]	Bit [11]	Bit [10]	Bit [9]	Bit [8]	Bit [7]	Bit [6]	Bit [5]	Bit [4]	Bit [3]	Bit [2]	Bit [1]	Bit [0]
rst	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

				ext trig	X ⁽³⁾	X ⁽³⁾	E3	E2	E1	ext trig	X ⁽³⁾	X ⁽³⁾	E3	E2	E1	
trig_clear ⁽⁴⁾	1	1	1	0	0	0	0	0	0	0	0	0	0	0	0	0
jne	1	0	0	0	1	0	0	Number of instructions to be skipped if the operation returns true				variable 1		variable 2		
jl	1	0	0	0	1	0	1	Number of instructions to be skipped if the operation returns true				variable 1		variable 2		
jge	1	0	0	0	1	1	0	Number of instructions to be skipped if the operation returns true				variable 1		variable 2		
je	1	0	0	0	1	1	1	Number of instructions to be skipped if the operation returns true				variable 1		variable 2		

- (1) This opcode is used with numerical operands.
- (2) This opcode is used with variables.
- (3) X means don't care.
- (4) This is a new instruction, not available in LP5523 or LP55231.

NAME	VALUE (d)	DESCRIPTION
loop count ⁽¹⁾	0–63	The number of loops to be done. 0 means an infinite loop.
step number	0–127	The step number to be loaded to program counter.
loop count ⁽²⁾	0–3	Selects the variable for loop count value. Loop count is loaded with the value of the variable defined below.
		0 = Local variable A
		1 = Local variable B
		2 = Global variable C
		3 = Global variable D

- (1) Valid for numerical operands.
- (2) Valid for variables.

8.5.2.6.2 INT

Send an interrupt to the processor by pulling the INT pin down and setting the corresponding status bit high. Interrupts can be cleared by reading the interrupt bits in the ENGINE_STATUS register at address 3Ch.

8.5.2.6.3 RST

The *rst* instruction resets the program counter register (address 30h, 31h, or 32h) and continues executing the program from the program the start address defined in register addresses 4Bh–4Dh. The instruction takes 16 32-kHz clock cycles. Note that default value for all program memory registers is 0000h, which is the *rst* instruction.

8.5.2.6.4 END

End program execution. The instruction takes 16 32-kHz clock cycles.

NAME	VALUE (d)	DESCRIPTION
int	0	No interrupt is sent. PWM register values remain intact.
	1	Reset program counter value to 0 and send interrupt to processor by pulling the INT pin down and setting the corresponding status bit high to notify that the program has ended. PWM register values remain intact. Interrupts can be cleared by reading the interrupt bits in STATUS/INTERRUPT register at address 3Ch.
reset	0	Reset program counter value to 0 and hold. PWM register values remain intact.
	1	Reset program counter value to 0 and hold. PWM register values of the non-mapped drivers remain. PWM register values of the mapped drivers are set to 0000 0000b.

8.5.2.6.5 TRIGGER and TRIG_CLEAR

The wait-for-trigger or send-a-trigger instruction can be used to synchronize operation between the program execution engines. Sending a trigger instruction takes 16 32-kHz clock cycles and waiting for a trigger takes at least 16 32-kHz clock cycles. The receiving engine stores the triggers that have been sent. Received triggers are cleared by the wait-for-trigger instruction or *trig_clear* instruction. The wait-for-trigger instruction is executed until all the defined triggers have been received. (Note: several triggers can be defined in the same instruction.) The external-trigger input signal must stay low for at least two 32-kHz clock cycles to be executed. The trigger output signal is three 32-kHz clock cycles long. The external trigger signal is active-low; for example, when a trigger is sent or received, the pin is pulled to GND. Sending an external trigger is masked; that is, the device which has sent the trigger does not recognize the trigger it sent. If send and wait external triggers are used on the same instruction, the send external trigger is executed first, followed by the wait external trigger.

The *trig_clear* instruction clears pending triggers for a single execution engine. Use this instruction in each execution engine at the beginning of program execution to clear any pending triggers. Pending triggers are always cleared whenever the engine mode is in the disabled state or load program to SRAM (see [SRAM Memory](#)).

NAME	VALUE (d)	DESCRIPTION
wait for trigger	0–31	Wait for trigger from the engine(s). Several triggers can be defined in the same instruction. Bit [7]: Wait for trigger from engine 1. Bit [8]: Wait for trigger from engine 2. Bit [9]: Wait for trigger from engine 3. Bit [12]: Wait for trigger from GPIO/TRIG/INT pin. Bits [10] and [11] are not used.
send a trigger	0–31	Send a trigger to the engine(s). Several triggers can be defined in the same instruction. Bit [1]: Send trigger to engine 1. Bit [2]: Send trigger to engine 2. Bit [3]: Send trigger to engine 3. Bit [6]: Send trigger to GPIO/TRIG/INT pin. Bits [4] and [5]: are not used.

8.5.2.6.6 JNE, JGE, JL, and JE

The LP5569 instruction set includes the following conditional jump instructions: jne (jump if not equal); jge (jump if greater or equal); jl (jump if less); je (jump if equal). If the condition is true, a certain number of instructions are skipped (that is, the program jumps forward to a location relative to the present location). If the condition is false, the next instruction is executed.

NAME	VALUE (d)	DESCRIPTION
Number of instructions to be skipped if the operation returns true.	0–31	The number of instructions to be skipped when the statement is true. Note: value 0 means redundant code.
variable 1	0–3	Defines the variable to be used in the test: 0 = Local variable A 1 = Local variable B 2 = Global variable C 3 = Global variable D

NAME	VALUE (d)	DESCRIPTION
variable 2	0–3	Defines the variable to be used in the test: 0 = Local variable A 1 = Local variable B 2 = Global variable C 3 = Global variable D

8.5.2.7 Data Transfer and Arithmetic Instructions

Table 13. LP5569 Data Transfer and Arithmetic Instructions

INST.	Bit [15]	Bit [14]	Bit [13]	Bit [12]	Bit [11]	Bit [10]	Bit [9]	Bit [8]	Bit [7]	Bit [6]	Bit [5]	Bit [4]	Bit [3]	Bit [2]	Bit [1]	Bit [0]

add ⁽²⁾	1	0	0	1	target variable		1	1	0	0	0	0	var 1		var 2	
sub ⁽¹⁾	1	0	0	1	target variable		1	0								
sub ⁽²⁾	1	0	0	1	target variable		1	1	0	0	0	1	var 1		var 2	

- (1) This opcode is used with numerical operands
- (2) This opcode is used with variables.

8.5.2.7.1 LD

This instruction is used to assign a value into a variable; the previous value in that variable is overwritten. Each of the engines has two local variables, called A and B. The variable C is a global variable.

NAME	VALUE (d)	DESCRIPTION
target variable	0–2	0 = Variable A 1 = Variable B 2 = Variable C
8-bit value	0–255	Variable value

8.5.2.7.2 ADD

This operator either adds an 8-bit value to the current value of the target variable, or adds the value of variable 1 (A, B, C, or D) to the value of variable 2 (A, B, C, or D) and stores the result in the register of variable A, B, or C. Variables overflow from 255 to 0.

NAME	VALUE (d)	DESCRIPTION
8-bit value ⁽¹⁾	0–255	The value to be added.
target variable	0–2	0 = Variable A 1 = Variable B 2 = Variable C
variable 1 ⁽²⁾	0–3	0 = Local variable A 1 = Local variable B 2 = Global variable C 3 = Global variable D
variable 2 ⁽²⁾	0–3	0 = Local variable A 1 = Local variable B 2 = Global variable C 3 = Global variable D

- (1) Valid for numerical operands.
- (2) Valid for variables.

8.5.2.7.3 SUB

The SUB operator either subtracts an 8-bit value from the current value of the target variable, or subtracts the value of variable 2 (A, B, C, or D) from the value of variable 1 (A, B, C, or D) and stores the result in the register of the target variable (A, B, or C). Variables overflow from 0 to 255.

NAME	VALUE (d)	DESCRIPTION
8-bit value ⁽¹⁾	0–255	The value to be subtracted.
target variable	0–2	0 = Variable A 1 = Variable B 2 = Variable C
variable 1 ⁽²⁾	0–3	0 = Local variable A 1 = Local variable B 2 = Global variable C 3 = Global variable D
variable 2 ⁽²⁾	0–3	0 = Local variable A 1 = Local variable B 2 = Global variable C 3 = Global variable D

(1) Valid for numerical operands

(2) Valid for variables

8.6 Register Maps

8.6.1 LP5569_MAP Registers

Table 14 lists the memory-mapped registers for the LP5569_MAP. All register offset addresses not listed in Table 14 should be considered as reserved locations and the register contents should not be modified.

Table 14. LP5569_MAP Registers

LED_ENGINE_CONTROL1 is shown in [Figure 28](#) and described in [Table 17](#).

Return to [Summary Table](#).

LED Engine Control Register 1

Execution states are defined in this register, and they are only applicable when the corresponding mode register in LED_ENGINE_CONTROL2 is set to the run mode. Execution-state values may be written by the host in other modes, but the engine disregards the write until the mode changes to run mode. The fields in this register define how the program is executed out of SRAM:

HOLD: The engine does not execute any instructions, but the program counter holds its current value unless overwritten by the host. This is the only state in which the PC can be written.

STEP: Executes a single instruction, increments the PC, and then changes to the hold state. If the instruction is a ramp or wait, the engine waits for this instruction to complete before changing to the hold state.

FREE RUN: The engine begins instruction execution from the current value of the PC. The program counter is reset to zero when its upper-limit value is reached at the top of SRAM memory.

EXECUTE ONCE: Executes a single instruction and then changes to the hold state. The PC remains unaffected unless the instruction is a branch command, in which case it changes if the branch is taken. If the instruction is a ramp or wait, it waits for this instruction to complete before changing to hold state.

8.6.1.3 LED_ENGINE_CONTROL2 Register (Address = 2h) [reset = 0h]

LED_ENGINE_CONTROL2 is shown in [Figure 29](#) and described in [Table 18](#).

Return to [Summary Table](#).

LED Engine Control Register 2

Operation modes are defined in this register.

DISABLED: Engines each can be configured to be disabled independently. When disabled, the program counter per ENGINE_x_PC is set to 0 and the engine does not execute instructions.

LOAD PROGRAM: Writing to program memory is allowed only when the engine is in the load-program operation mode and the engine-busy bit (register 3C) is not set. The host should check the engine-busy bit before writing to program memory or allow at a least 1-ms delay after entering the load mode before memory write, to ensure initialization. If any engine is set to the load-program mode, then the other engines should be set either to the disabled or load-program mode, because they are inhibited from executing instructions while loading the SRAM. The load-program mode also resets the program counter of the respective engine. The load-program mode can only be entered from the disabled mode.

RUN PROGRAM: The run-program mode executes the instructions stored in the program memory. Execution register (LED_ENGINE_CONTROL1) bits define how the program is executed (hold, step, free-run or execute once).

HALT: Instruction execution aborts immediately and engine operation halts.

R/W-0h			R/W-0h	R/W-0h	R/W-1h		R/W-0h

Table 50. MISC2 Register Field Descriptions

Bit	Field	Type	Reset	Description
7–5	RESERVED	R/W	0h	Reserved
4	led_short_test	R/W	0h	0 = LED-short test disabled (default) 1 = LED-short test enabled
3	led_open_test	R/W	0h	0 = LED-open test disabled (default) 1 = LED-open test enabled
2–1	led_headroom	R/W	1h	Selectable low-headroom comparator settings: 00 = 200 mV 01 = 250 mV (default) 10 = 300 mV 11 = 250 mV
0	cp_dis_disch	R/W	0h	Charge pump discharge disable. 0 = discharging is enabled in shutdown and standby states, absent of TSD. (default) 1 = discharging is disabled

8.6.1.36 ENGINE_STATUS Register (Address = 3Ch) [reset = 80h]

ENGINE_STATUS is shown in [Figure 62](#) and described in [Table 51](#).

Return to [Summary Table](#).

Engine Status Register

Figure 62. ENGINE_STATUS Register

7	6	5	4	3	2	1	0
mask_busy	startup_busy	engine_busy	RESERVED		ch3_int	ch2_int	ch1_int
R/W-1h	R-0h	R-0h	R-0h		R-0h	R-0h	R-0h

Table 51. ENGINE_STATUS Register Field Descriptions

Bit	Field	Type	Reset	Description
7	mask_busy	R/W	1h	Mask bit for interrupts generated by START-UP_BUSY or ENGINE_BUSY. 0 = External interrupt is generated when START-UP_BUSY or ENGINE_BUSY condition is no longer true. 1 = Interrupt events are masked (no external interrupt generated by START-UP_BUSY or ENGINE_BUSY). Reading register 3Ch clears the status bits and releases the INT pin to the high state.

Table 51. ENGINE_STATUS Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
6	startup_busy	R	0h	A status bit which indicates that the device is running the internal start-up sequence. 0 = Internal start-up sequence completed. 1 = Internal start-up sequence running
5	engine_busy	R	0h	A status bit which indicates that a program execution engine is clearing internal registers. Serial bus master should not write or read program memory, or registers 30h to 32h or 4Bh to 4Dh, when this bit is set to 1. 0 = All engines ready 1 = At least one of the engines is clearing internal registers.
4–3	RESERVED	R	0h	Reserved
2	ch3_int	R	0h	Engine3 interrupt. 0 = Interrupt cleared 1 = Interrupt set Interrupt is set by the END or INT instruction. Reading the ENGINE_STATUS address clears the interrupt.
1	ch2_int	R	0h	Engine2 interrupt. 0 = Interrupt cleared 1 = Interrupt set Interrupt is set by the END or INT instruction. Reading the ENGINE_STATUS address clears the interrupt.
0	ch1_int	R	0h	Engine1 interrupt. 0 = Interrupt cleared 1 = Interrupt set Interrupt is set by the END or INT instruction. Reading the ENGINE_STATUS address clears the interrupt.

8.6.1.37 IO_CONTROL Register (Address = 3Dh) [reset = 2h]

IO_CONTROL is shown in [Figure 63](#) and described in [Table 52](#).

Return to [Summary Table](#).

I/O Control Register

Figure 63. IO_CONTROL Register

9 Application and Implementation

NOTE

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

9.1 Application Information

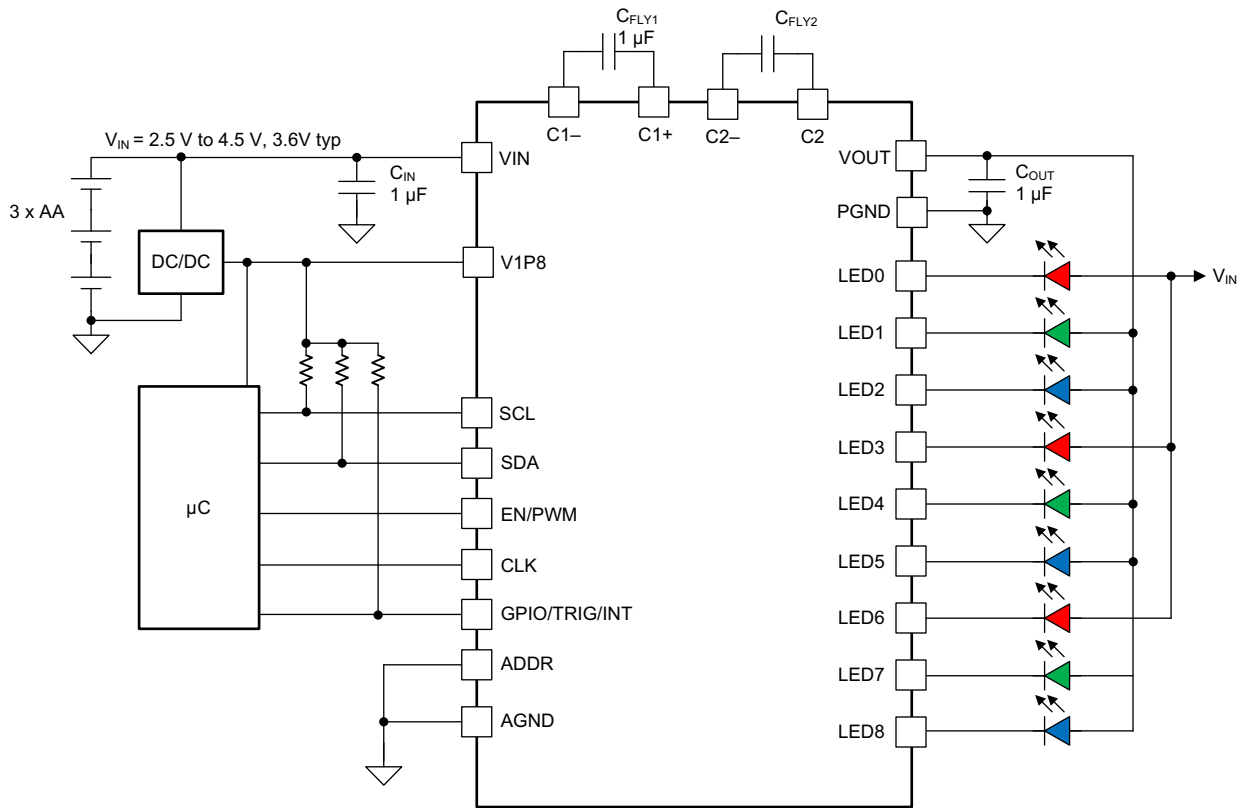

The LP5569 device is designed as an autonomous lighting controller for handheld devices. In these devices, extremely small form factor is needed; therefore, the LP5569 device is designed to require only four small capacitors: input and output, as well as flying capacitor 1 and flying capacitor 2 for the charge pump. If the system has other LED input voltages available, and the charge pump is not needed in the application, the charge-pump capacitors can be omitted, thus reducing the solution even further. The device can drive RGB LEDs or discrete LEDs of any color if desired.

9.2 Typical Applications

9.2.1 Single LP5569 Application

Figure 119 shows an example of a typical application that uses a charge pump to get high-enough voltage to drive green and blue LEDs. Red LEDs are powered from V_{VIN} for reduced power consumption. The device, with a voltage range of 2.5 V to 4.5 V, is powered from three AA batteries, typically 3.6 V with 1.2-V cell voltage. *Design Requirements* shows related design parameters for this example. In this example, input voltage with AA batteries is typically over 3.6 V (cell voltage >1.2 V) for half of the battery lifetime. During this time the charge pump operates in 1x mode, as the input voltage is enough for the green and blue LEDs. As the battery voltage continues to decrease, the LP5569 device detects that the LED headroom voltage is too low and automatically configures the charge pump to the 1.5x mode. In 1.5x mode, the LEDs can be powered with V_{IN} down to 2.5 V, where the batteries are almost empty.

Typical Applications (continued)

Copyright © 2017, Texas Instruments Incorporated

Figure 119. LP5569 Typical Application

9.2.1.1 Design Requirements

DESIGN PARAMETER	EXAMPLE VALUE
Input voltage range	2.5 V to 5.5 V
LED V_F (maximum)	3.2 V
LED current	25.5 mA maximum
Input capacitor	$C_{IN} = 1 \mu F$
Output capacitor	$C_{OUT} = 1 \mu F$
Charge pump flying capacitors	$C_{FLY1} = C_{FLY2} = 1 \mu F$
Charge-pump mode	1.5x or automatic

9.2.1.2 Detailed Design Procedure

The LP5569 device requires four external capacitors for proper operation. TI recommends surface-mount multi-layer ceramic capacitors. Tantalum and aluminum capacitors are not recommended because of their high ESR. Multi-layer ceramic capacitors must always be used for the flying capacitors (C_{FLY1} and C_{FLY2}). Ceramic capacitors with an X7R or X5R temperature characteristic are preferred for use with the LP5569 device. These capacitors have tight capacitance tolerance (as good as $\pm 10\%$) and hold their value over temperature (X7R: $\pm 15\%$ over $-55^\circ C$ to $125^\circ C$; X5R: $\pm 15\%$ over $-55^\circ C$ to $85^\circ C$).

It is necessary to have at least $0.24 \mu F$ of effective capacitance for each of the flying capacitors under all operating conditions to ensure proper operation. The output capacitor C_{OUT} directly affects the magnitude of the output ripple voltage. In general, the higher the value of C_{OUT} , the lower the output-ripple magnitude. For proper operation TI recommends having at least $0.5 \mu F$ of effective capacitance for C_{IN} and C_{OUT} under all operating conditions. The voltage rating of all four capacitors must be 6.3 V (minimum), with 10 V preferred.

Table 108 lists suitable external components from some leading ceramic capacitor manufacturers.

Table 108. Suitable External Components

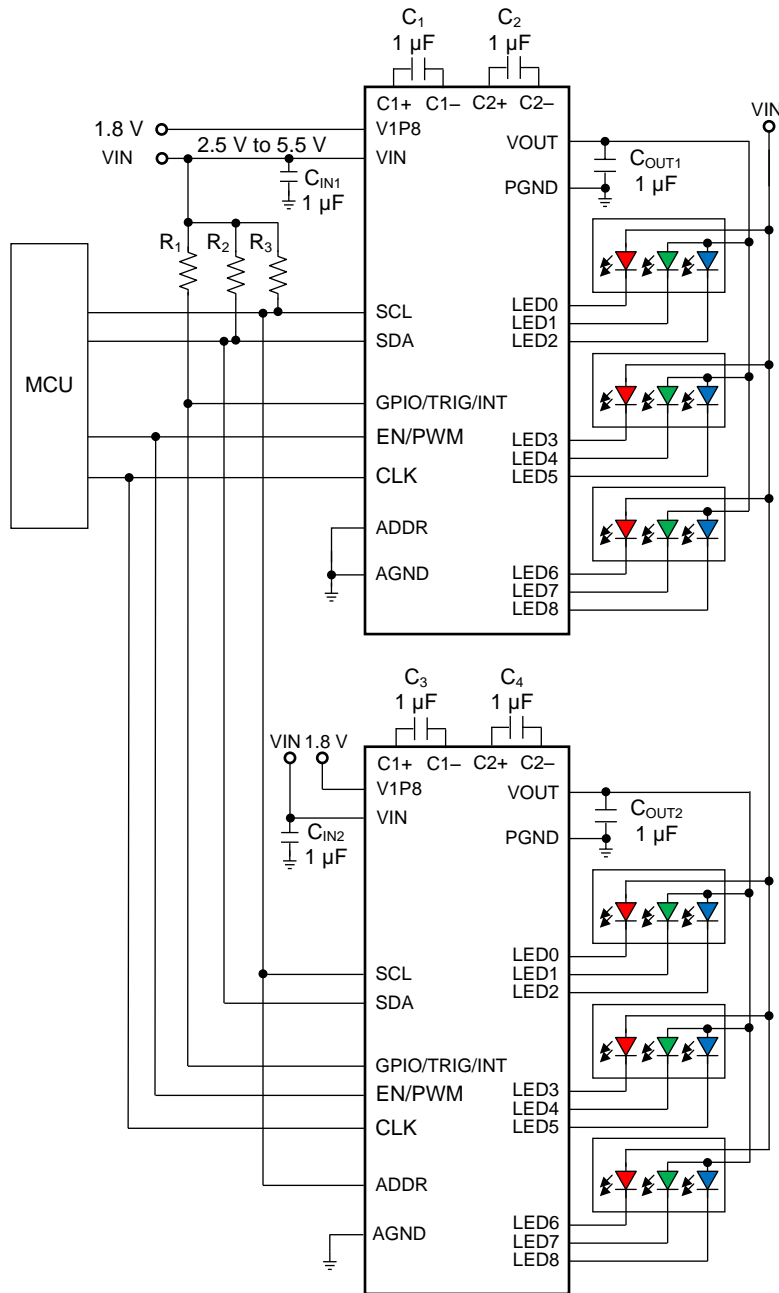

MODEL	TYPE	VENDOR	VOLTAGE RATING (V)	PACKAGE SIZE
C1005X5R1A105K	Ceramic X5R	TDK	10	0402
LMK105BJ105KV-F	Ceramic X5R	Taiyo Yuden	10	0402
ECJ0EB1A105M	Ceramic X5R	Panasonic	10	0402

9.2.1.3 Application Curves

9.2.2 Using Multiple LP5569 Devices

The LP5569 device enables up to eight parallel devices together, which can drive up to 24 RGB LEDs or 72 single LEDs. Figure 122 shows the connections for two LP5569 devices for six RGB LEDs. Note that the LED6, LED7, and LED8 outputs are used for the red LEDs. The SCL and SDA lines must each have a pullup resistor placed somewhere on the line (R2 and R3; the pullup resistors are normally located on the bus master). In typical applications, values of 1.8 kΩ to 4.7 kΩ are used, depending on the bus capacitance, I/O voltage, and the desired communication speed. GPIO/TRIG/INT is open drain, which requires a pullup resistor. The typical value for R1 is from 120 kΩ to 180 kΩ for two LP5569 devices.

Figure 122. Dual LP5569 Application Example

9.2.2.1 Design Requirements

DESIGN PARAMETER	EXAMPLE VALUE
Input voltage range	2.5 V to 5.5 V
LED V_F (maximum)	3.2 V
LED current	25.5 mA maximum
Input capacitor	$C_{IN} = 1 \mu F$
Output capacitor	$C_{OUT} = 1 \mu F$
Charge pump flying capacitors	$C_{FLY1} = C_{FLY2} = 1 \mu F$
Charge-pump mode	1.5x or automatic

9.2.2.2 Detailed Design Procedure

External component selection follows the earlier example (see [Detailed Design Procedure](#)).

9.2.2.3 Application Curves

10 Power Supply Recommendations

The device is designed to operate from a V_{VIN} input-voltage supply range between 2.5 V and 5.5 V. This input supply must be well-regulated and able to withstand maximum input current and maintain stable voltage without voltage drop even in a load-transition condition (start-up or rapid brightness change). The resistance of the input supply rail must be low enough that the input-current transient does not cause a drop below 2.5-V in the LP5569 V_{VIN} supply voltage.

11 Layout

11.1 Layout Guidelines

The charge pump basically has three areas of concern regarding component placement:

- The flying capacitors
- The output capacitor
- The input capacitor

11.1.1 Flying Capacitor Placement

The charge pump flying capacitors must quickly charge up and then supply current to the output every switching cycle. Because the charge-pump switching frequency is 1.25 MHz, the capacitor must be a low-inductance and low-resistance ceramic. Additionally, there must be a low-inductive connection between the flying capacitors and LP5569 pins C1P, C2P, C1M, and C2M.

11.1.2 Output Capacitor Placement

The charge-pump output capacitor is charged by the flying capacitor every switching cycle (1.25 MHz). This fast switching action requires that a low-inductance and low-resistance capacitor (ceramic) be used and that the output capacitor be connected to the LP5569 VOUT pin with a low-inductance connection. This is done by placing the output capacitor as close as possible to the VOUT and PGND pins of the LP5569 device, with connections on the same layer to avoid vias.

11.1.3 Input Capacitor Placement

The charge pump input capacitor is discharged by the flying capacitor every switching cycle (0.8 μ s). This fast switching action requires that a low-inductance and low-resistance capacitor (ceramic) be used and that the input capacitor be connected to the LP5569 VIN pin with a low-inductive connection. This is done by placing the output capacitor as close as possible to the VOUT and AGND pins of the LP5569 device, with connections on the same layer to avoid vias.

12 Device and Documentation Support

12.1 Device Support

12.1.1 Third-Party Products Disclaimer

TI'S PUBLICATION OF INFORMATION REGARDING THIRD-PARTY PRODUCTS OR SERVICES DOES NOT CONSTITUTE AN ENDORSEMENT REGARDING THE SUITABILITY OF SUCH PRODUCTS OR SERVICES OR A WARRANTY, REPRESENTATION OR ENDORSEMENT OF SUCH PRODUCTS OR SERVICES, EITHER ALONE OR IN COMBINATION WITH ANY TI PRODUCT OR SERVICE.

12.2 Receiving Notification of Documentation Updates

To receive notification of documentation updates, navigate to the device product folder on ti.com. In the upper right corner, click on *Alert me* to register and receive a weekly digest of any product information that has changed. For change details, review the revision history included in any revised document.

12.3 Community Resources

The following links connect to TI community resources. Linked contents are provided "AS IS" by the respective contributors. They do not constitute TI specifications and do not necessarily reflect TI's views; see TI's [Terms of Use](#).

TI E2E™ Online Community *TI's Engineer-to-Engineer (E2E) Community*. Created to foster collaboration among engineers. At e2e.ti.com, you can ask questions, share knowledge, explore ideas and help solve problems with fellow engineers.

Design Support *TI's Design Support* Quickly find helpful E2E forums along with design support tools and contact information for technical support.

12.4 Trademarks

E2E is a trademark of Texas Instruments.
Bluetooth is a registered trademark of Bluetooth SIG, Inc..
All other trademarks are the property of their respective owners.

12.5 Electrostatic Discharge Caution

These devices have limited built-in ESD protection. The leads should be shorted together or the device placed in conductive foam during storage or handling to prevent electrostatic damage to the MOS gates.

12.6 Glossary

[SLYZ022](#) — *TI Glossary*.

This glossary lists and explains terms, acronyms, and definitions.

13 Mechanical, Packaging, and Orderable Information

The following pages include mechanical, packaging, and orderable information. This information is the most-current data available for the designated device. This data is subject to change without notice and without revision of this document. For browser-based versions of this data sheet, see the left-hand navigation pane.

PACKAGING INFORMATION

Orderable Device	Status (1)	Package Type	Package Drawing	Pins	Package Qty	Eco Plan (2)	Lead/Ball Finish (6)	MSL Peak Temp (3)	Op Temp (°C)	Device Marking (4/5)	Samples
LP5569RTWR	ACTIVE	WQFN	RTW	24	3000	Green (RoHS & no Sb/Br)	CU NIPDAU	Level-2-260C-1 YEAR	-40 to 85	5569	Samples

(1) The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

OBSOLETE: TI has discontinued the production of the device.

(2) **RoHS:** TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".

RoHS Exempt: TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.

Green: TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead/Ball Finish - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead/Ball Finish values may wrap to two lines if the finish value exceeds the maximum column width.

IMPORTANT NOTICE

Texas Instruments Incorporated (TI) reserves the right to make corrections, enhancements, improvements and other changes to its semiconductor products and services per JESD46, latest issue, and to discontinue any product or service per JESD48, latest issue. Buyers should obtain the latest relevant information before placing orders and should verify that such information is current and complete.

TI's published terms of sale for semiconductor products (<http://www.ti.com/sc/docs/stdterms.htm>) apply to the sale of packaged integrated circuit products that TI has qualified and released to market. Additional terms may apply to the use or sale of other types of TI products and services.

Reproduction of significant portions of TI information in TI data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. TI is not responsible or liable for such reproduced documentation. Information of third parties may be subject to additional restrictions. Resale of TI products or services with statements different from or beyond the parameters stated by TI for that product or service voids all express and any implied warranties for the associated TI product or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

Buyers and others who are developing systems that incorporate TI products (collectively, "Designers") understand and agree that Designers remain responsible for using their independent analysis, evaluation and judgment in designing their applications and that Designers have full and exclusive responsibility to assure the safety of Designers' applications and compliance of their applications (and of all TI products used in or for Designers' applications) with all applicable regulations, laws and other applicable requirements. Designer represents that, with respect to their applications, Designer has all the necessary expertise to create and implement safeguards that (1) anticipate dangerous consequences of failures, (2) monitor failures and their consequences, and (3) lessen the likelihood of failures that might cause harm and take appropriate actions. Designer agrees that prior to using or distributing any applications that include TI products, Designer will thoroughly test such applications and the functionality of such TI products as used in such applications.

TI's provision of technical, application or other design advice, quality characterization, reliability data or other services or information, including, but not limited to, reference designs and materials relating to evaluation modules, (collectively, "TI Resources") are intended to assist designers who are developing applications that incorporate TI products; by downloading, accessing or using TI Resources in any way, Designer (individually or, if Designer is acting on behalf of a company, Designer's company) agrees to use any particular TI Resource solely for this purpose and subject to the terms of this Notice.

TI's provision of TI Resources does not expand or otherwise alter TI's applicable published warranties or warranty disclaimers for TI products, and no additional obligations or liabilities arise from TI providing such TI Resources. TI reserves the right to make corrections, enhancements, improvements and other changes to its TI Resources. TI has not conducted any testing other than that specifically described in the published documentation for a particular TI Resource.

Designer is authorized to use, copy and modify any individual TI Resource only in connection with the development of applications that include the TI product(s) identified in such TI Resource. NO OTHER LICENSE, EXPRESS OR IMPLIED, BY ESTOPPEL OR OTHERWISE TO ANY OTHER TI INTELLECTUAL PROPERTY RIGHT, AND NO LICENSE TO ANY TECHNOLOGY OR INTELLECTUAL PROPERTY RIGHT OF TI OR ANY THIRD PARTY IS GRANTED HEREIN, including but not limited to any patent right, copyright, mask work right, or other intellectual property right relating to any combination, machine, or process in which TI products or services are used. Information regarding or referencing third-party products or services does not constitute a license to use such products or services, or a warranty or endorsement thereof. Use of TI Resources may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

TI RESOURCES ARE PROVIDED "AS IS" AND WITH ALL FAULTS. TI DISCLAIMS ALL OTHER WARRANTIES OR REPRESENTATIONS, EXPRESS OR IMPLIED, REGARDING RESOURCES OR USE THEREOF, INCLUDING BUT NOT LIMITED TO ACCURACY OR COMPLETENESS, TITLE, ANY EPIDEMIC FAILURE WARRANTY AND ANY IMPLIED WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE, AND NON-INFRINGEMENT OF ANY THIRD PARTY INTELLECTUAL PROPERTY RIGHTS. TI SHALL NOT BE LIABLE FOR AND SHALL NOT DEFEND OR INDEMNIFY DESIGNER AGAINST ANY CLAIM, INCLUDING BUT NOT LIMITED TO ANY INFRINGEMENT CLAIM THAT RELATES TO OR IS BASED ON ANY COMBINATION OF PRODUCTS EVEN IF DESCRIBED IN TI RESOURCES OR OTHERWISE. IN NO EVENT SHALL TI BE LIABLE FOR ANY ACTUAL, DIRECT, SPECIAL, COLLATERAL, INDIRECT, PUNITIVE, INCIDENTAL, CONSEQUENTIAL OR EXEMPLARY DAMAGES IN CONNECTION WITH OR ARISING OUT OF TI RESOURCES OR USE THEREOF, AND REGARDLESS OF WHETHER TI HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

Unless TI has explicitly designated an individual product as meeting the requirements of a particular industry standard (e.g., ISO/TS 16949 and ISO 26262), TI is not responsible for any failure to meet such industry standard requirements.

Where TI specifically promotes products as facilitating functional safety or as compliant with industry functional safety standards, such products are intended to help enable customers to design and create their own applications that meet applicable functional safety standards and requirements. Using products in an application does not by itself establish any safety features in the application. Designers must ensure compliance with safety-related requirements and standards applicable to their applications. Designer may not use any TI products in life-critical medical equipment unless authorized officers of the parties have executed a special contract specifically governing such use. Life-critical medical equipment is medical equipment where failure of such equipment would cause serious bodily injury or death (e.g., life support, pacemakers, defibrillators, heart pumps, neurostimulators, and implantables). Such equipment includes, without limitation, all medical devices identified by the U.S. Food and Drug Administration as Class III devices and equivalent classifications outside the U.S.

TI may expressly designate certain products as completing a particular qualification (e.g., Q100, Military Grade, or Enhanced Product). Designers agree that it has the necessary expertise to select the product with the appropriate qualification designation for their applications and that proper product selection is at Designers' own risk. Designers are solely responsible for compliance with all legal and regulatory requirements in connection with such selection.

Designer will fully indemnify TI and its representatives against any damages, costs, losses, and/or liabilities arising out of Designer's non-compliance with the terms and provisions of this Notice.
